

The MACC global reanalysis

An eight-year dataset (2003-2010) on atmospheric composition (and meteorology)

The ECMWF project team (Anna Agusti-Panareda, Angela Benedetti, Johannes Flemming, Richard Engelen, Antje Inness, Johannes Kaiser, Luke Jones, Jean-Jacques Morcrette, Miha Razinger, Adrian Simmons and Martin Suttie) and many other project members at partner institutions

with acknowledgment to Tony Hollingsworth (1943-2007)

MACC was a contribution to Europe's global monitoring initiative GMES

The atmospheric programme of GMES comprises

- implementing operational space-based observation of atmospheric composition
- strengthening complementary *in situ* observation
- developing and operating associated monitoring and forecasting services

MACC was a 48-partner project co-funded by the European Union

- to be the pilot (2009-2011) for the atmospheric monitoring/forecasting services
- as the counterpart of the ocean-service project MyOcean
- building on earlier GEMS and PROMOTE projects of the EU and ESA
- with most activities continuing in MACC-II (2012 – 2014)

GMES atmospheric services relate to chemical and particulate concentrations

Weather agencies

**GMES
atmospheric
services**

provide data and
information on

**Emissions and
climate forcing by
greenhouse gases
and aerosols**

**Long-range pollutant
transport**

European air quality

Dust outbreaks

Biomass burning

Solar energy

UV radiation

...

**Environmental
agencies**

Transport by winds

Chemical reactions

- dependent on sunlight, temperature, humidity, cloud particles, ...

Deposition

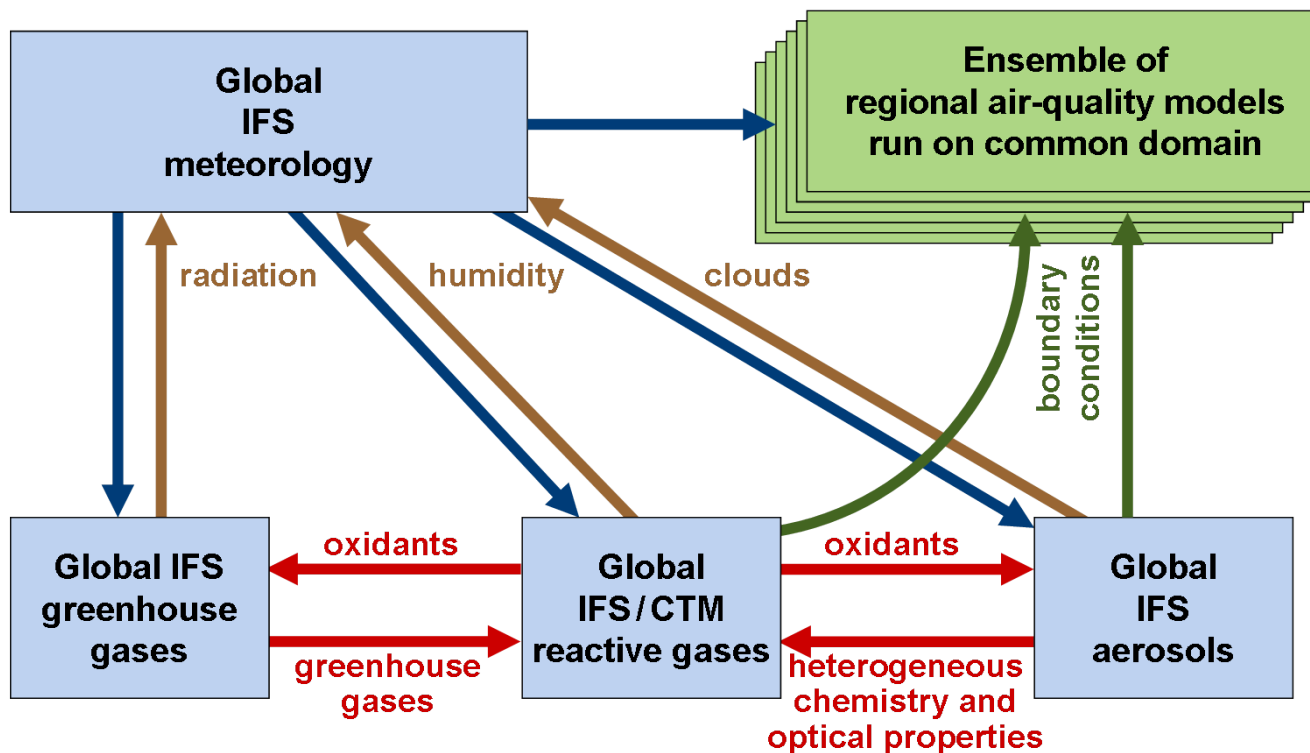

- dependent on turbulence, rainfall, ...

Uptake by vegetation, soils and oceans

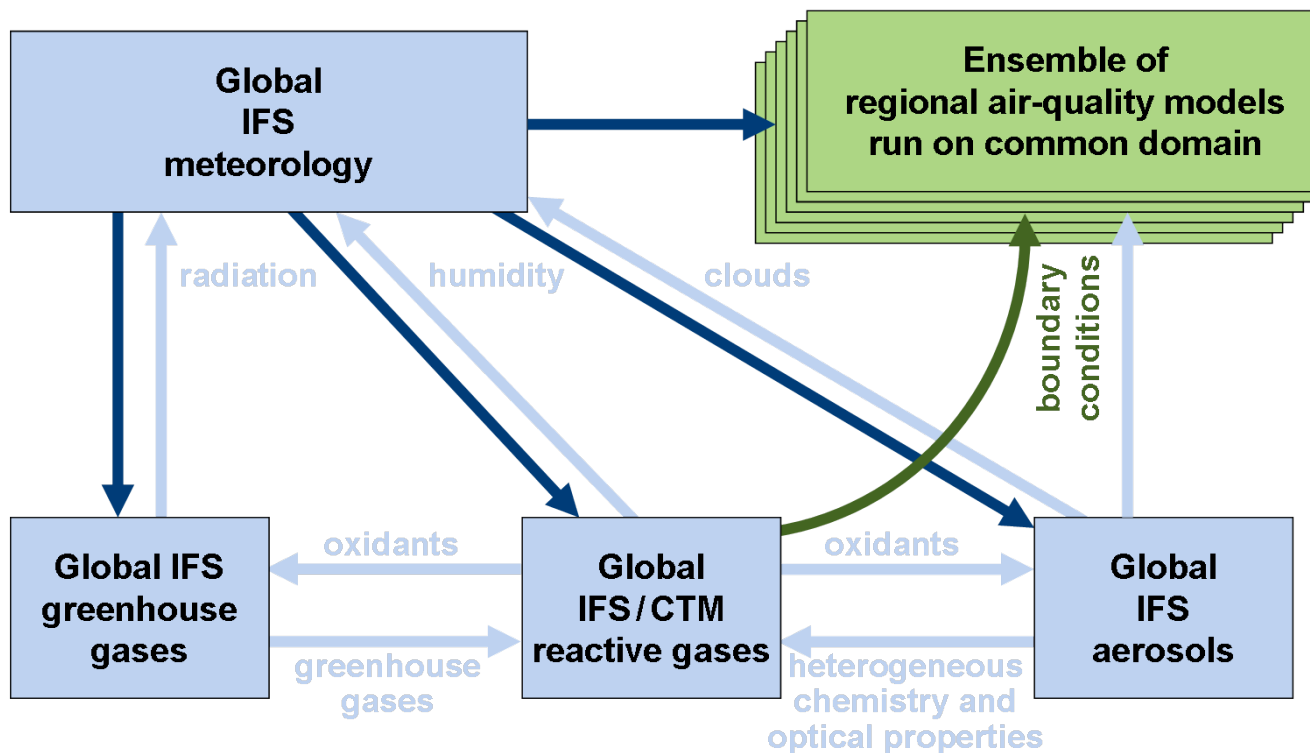

- dependent on rainfall, temperature, wind, ...

Global system is based on the ECMWF Integrated Forecasting System (IFS), coupled to a global chemical transport model (CTM: **MOZART**, TM5 or MOCAGE)

Regional ensemble comprises seven CTMs run on a common European domain

Monthly zonal-mean distributions of CO₂, CH₄ and O₃ from an earlier reanalysis undertaken in the GEMS project are used in the IFS' s radiation scheme

Approach is based on the 4D-Var scheme of the IFS

Meteorological data are assimilated together with data on constituents

CO₂, CH₄ and aerosols are incorporated in the IFS

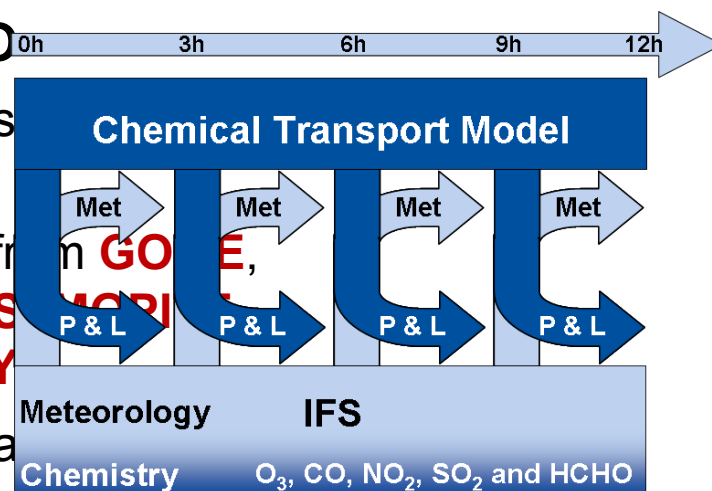

Assimilated data are **AIRS** and IASI radiances, **SCIAMACHY** retrievals, **MODIS** aerosol optical depth, GOSAT ...

IFS also carries O₃, CO, NO₂, SO₂ and HCHO

Chemical production and loss in the coupled CTM

Data for assimilation come from **GOES**, **GOME-2**, **IASI**, **MIPAS**, **MLS**, **OMI**, **SBUV/2**, **SCIAMACHY**

Chemistry is being incorporated

Emissions from fires are analysed

Based on fire radiative power products from **MODIS** and

Daily monitoring and forecasting

- global system
- ensemble of regional systems

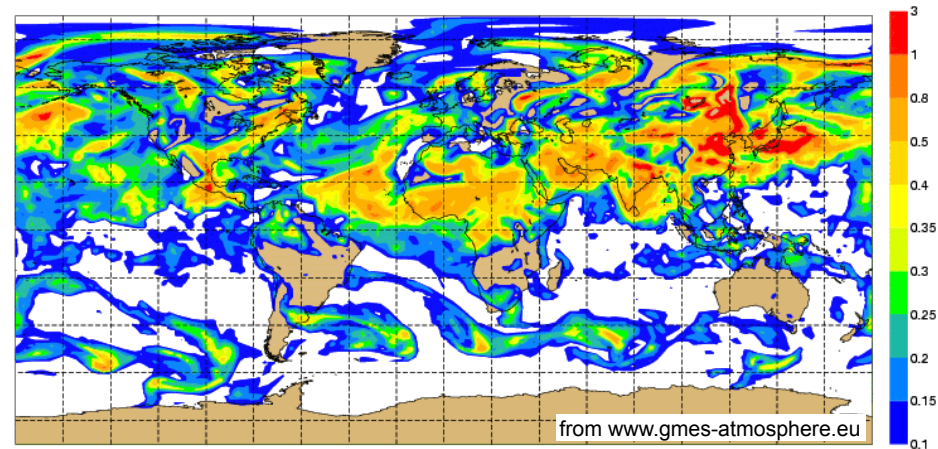

Delayed-mode analysis

- global system is run again about six months behind time for CO₂, CH₄ and aerosols
- allows assimilation of delayed data, and use of higher horizontal resolution
- particularly for estimation of surface-flux corrections

Reanalysis

- global, for 2003-2010, using same resolution as ERA-Interim but newer (January 2010) version of forecasting system
- regional, 2007 onwards, using ensemble of regional systems assimilating validated air-quality data, for annual assessment of European air quality

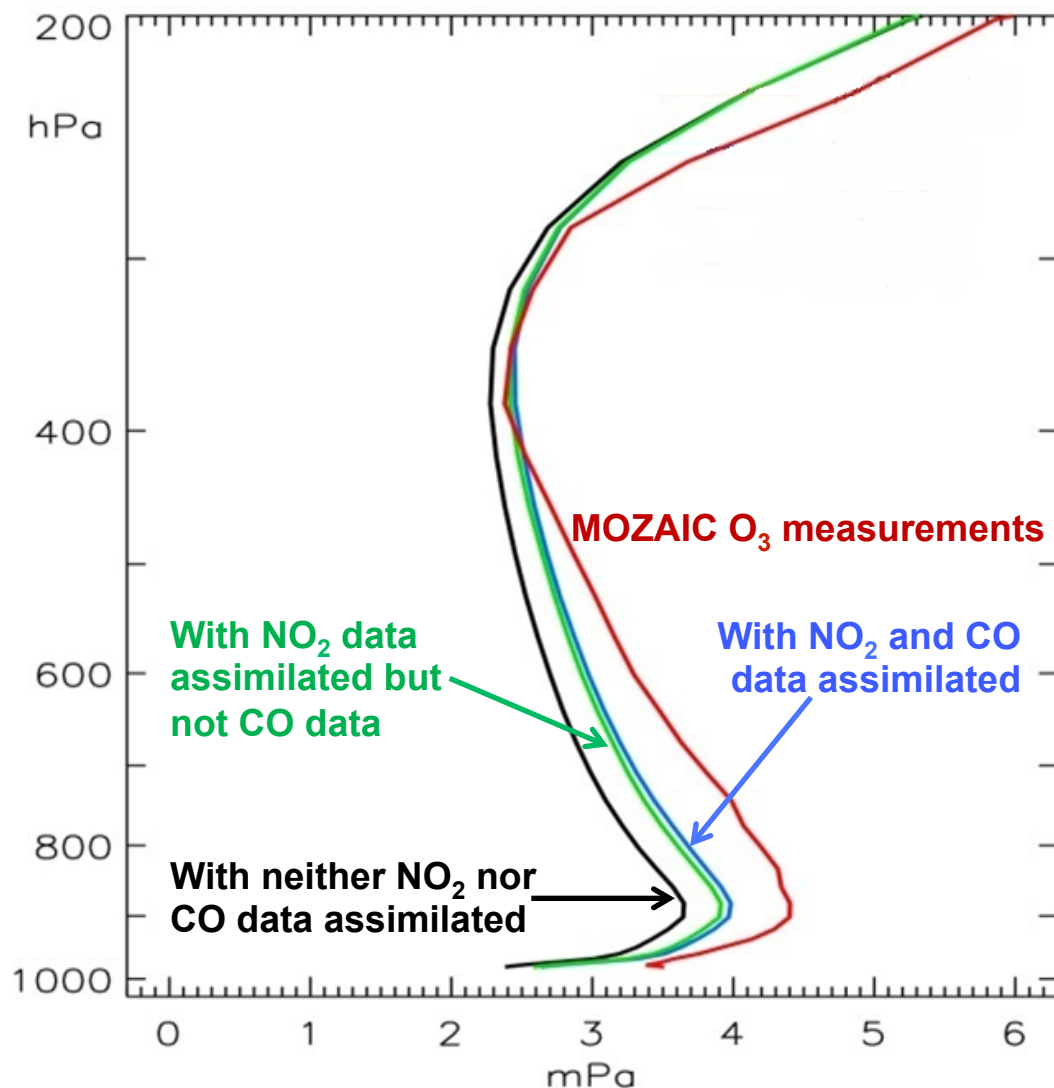

Wednesday 9 May 2012 00UTC MACC Forecast t+003 VT: Wednesday 9 May 2012 03UTC
Total Aerosol Optical Depth at 550 nm

Comparison of MACC analyses
with mean ozone profile from 371
ascents or descents of MOZAIC
aircraft at Frankfurt from
February to June, 2003

Ozone data are assimilated in
each of the three cases shown

The analysis system is univariate
for composition variables, but
assimilation of NO_2 and to a
lesser extent CO data improves
the background forecast for
ozone, and consequently the fit of
the analysis to the independent
MOZAIC data

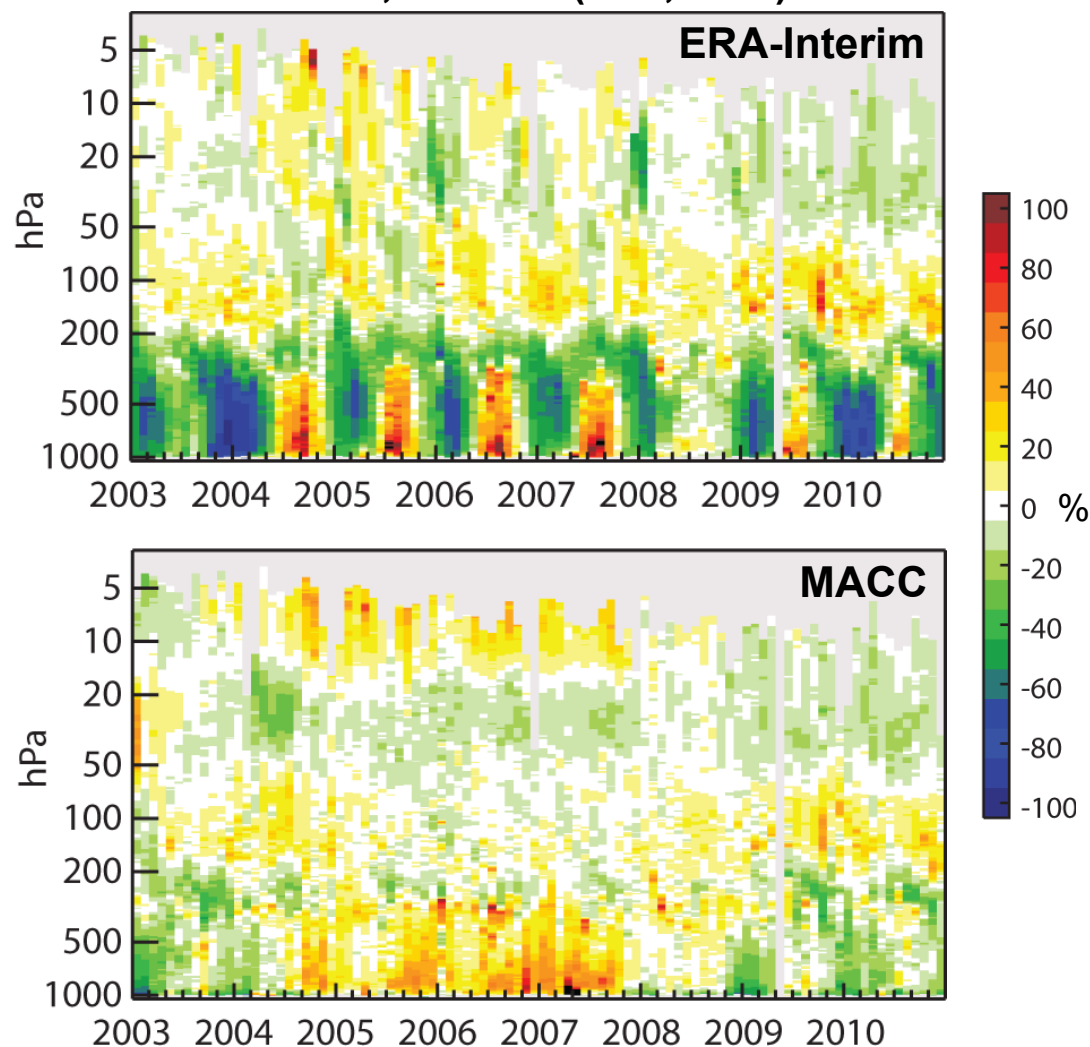

Monthly-mean differences between reanalyses and ozonesonde data

The MOZART chemistry used by MACC generally outperforms the much simpler Cariolle scheme used in ERA-Interim

Bias correction of MLS data was turned off in MACC reanalysis from 1 Jan 2008 to prevent drift in lower tropospheric and upper stratospheric ozone

Alert, Canada (82N, 62W)

- Station values from NOAA/ESRL
- MACC reanalysis
- Control run of MOZART CTM

Control run of CTM underestimates CO

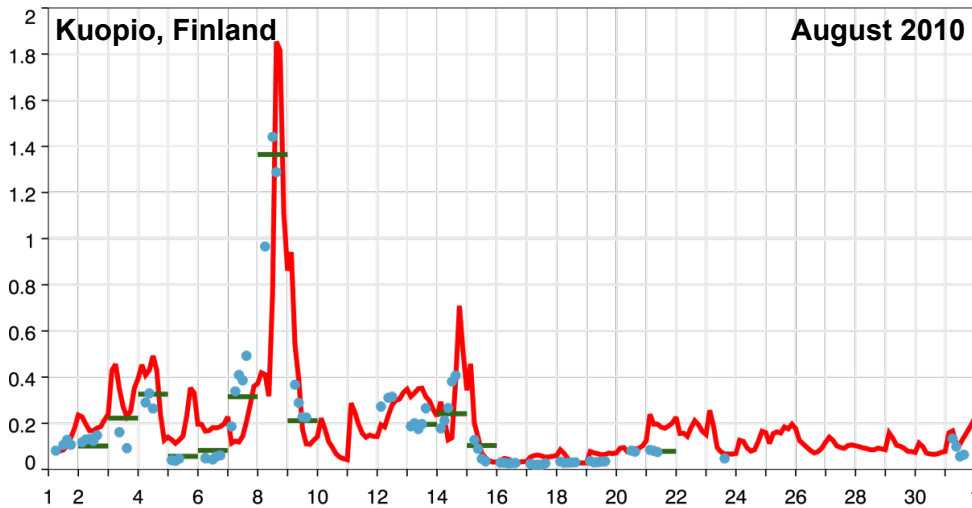

A problem with the model or the specified emissions?

Changes in the reanalysis in 2008 most likely come from the assimilation of CO data from IASI (in addition to those from MOPITT)

Comparison of aerosol optical depth at ~500nm with AERONET data

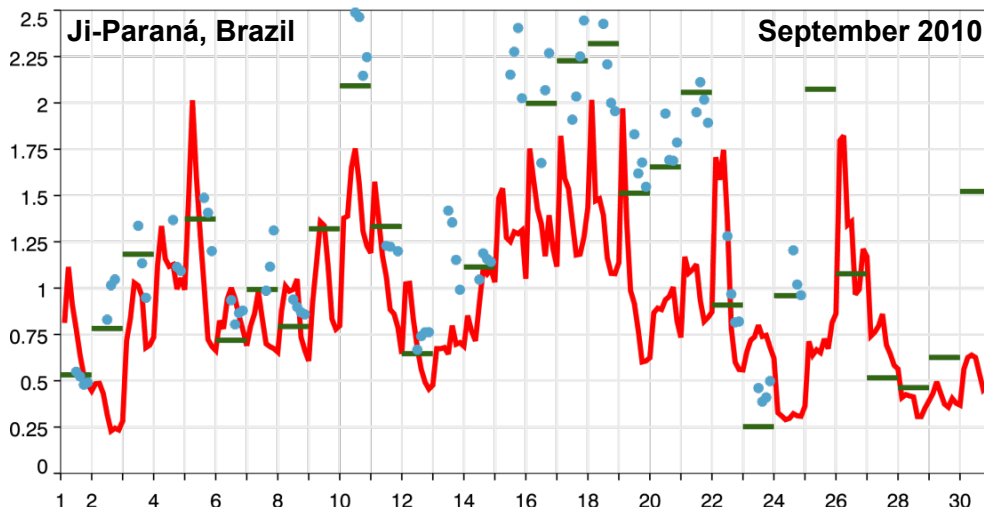

● AERONET — MODIS — MACC (3h - 24h)

Anchoring flask data

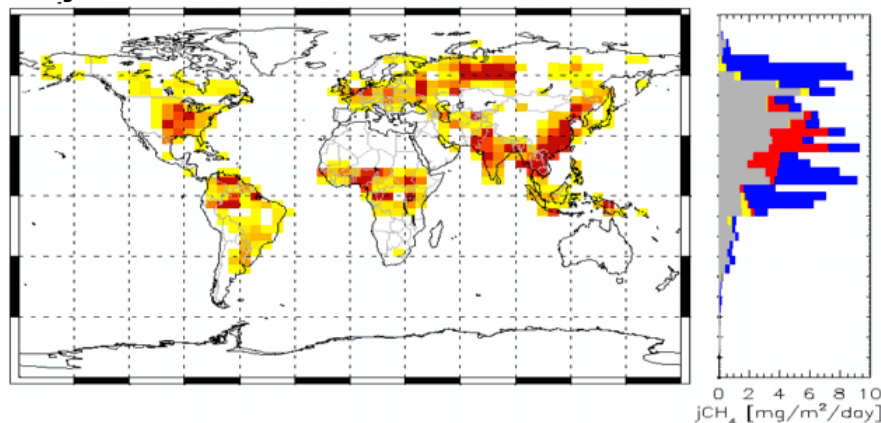

NOAA Earth System Research Laboratory global cooperative air sampling network

Prior modelled emissions

Adjusted emissions

July 2009

MACC was a substantial effort of which global reanalysis was a part

The reanalysis was carried out with a relatively new system

- which shows a reasonable degree of success
- with data available from ECMWF public server and some partners' servers
- to be used with caution for some species (e.g. CO₂ and low-level O₃)
- to be extended beyond 2010 in MACC-II, but rerun only for limited periods
- to gain in computational efficiency from incorporating all chemistry in IFS

Future progress of the whole activity requires commitments

- from Europe to Sentinel satellite series as well as monitoring/forecasting service
- from nations to ground-based and airborne measurement systems for atmospheric composition
- with addressing the gap in provision of limb sounding a further need

There is scope for further integration of other Earth-system components
