

**USE OF REANALYSES TO EXAMINE
CLIMATE MODEL ERRORS
IN SHORT FORECASTS**

David L. Williamson

**National Center for Atmospheric Research
Boulder, Colorado, USA**

Forecasts with climate models

**from operational analyses and reanalyses
at climate model production resolution**

Gain insight into parameterization errors

**by comparing parameterized variables to estimates
from field campaigns (e.g. ARM)
when states fed to parameterizations are still
close to atmospheric analyses**

Also useful just to examine model state errors

compared to reanalyses

sensitivity studies to address hypotheses

Benefit of using multiple reanalyses:

**Establish sensitivity to different analyses
parameterizations and dynamics behaviors**

Native analysis can bias the results

SPIN-UP DURING FORECAST

NWP goal – make best possible forecast of evolving weather

Spin-up of precipitation is common problem

occurs because model is inconsistent with analyses

Precipitation ignored for first few hours of forecast

Our goal – gain insight into model errors

Spin-up is primary signal

Problem – analysis errors might contribute to spin-up

MERRA IC

**Relatively inexpensive approach to examine primary errors
before climate balancing occurs**

Should have reanalysis on native grid

Allows experiments that might not survive long climate runs

Useful for sensitivity studies against reanalyses alone

**Forecasts exposed a flaw in the model
strong precipitation cells**

**Analysis of the model processes during the forecast
reveals the source of that problem**

Can eliminate that problem

Others remain with less obvious causes

Examine state errors based on reanalyses

How can we tell which are reliable and which to use?

Simple first order statements like

Observations did affect the analysis in this area

Analysis is very close to model first guess

Community should make quality comparisons

and advise potential users on what the analyses

should and should not be used for
