Sub-millimeter-wave receivers employing super sensitive SIS (Superconductor-Insulator-Superconductor) detector technology provide new opportunities for precise passive remote sensing observations of minor constituents in the atmosphere. The Superconducting Submillimeter-Wave Limb-Emission Sounder (SMILES) was launched on September 11, 2009 and is installed on board the Japanese Experiment Module (JEM) of the International Space Station (ISS). SMILES is a collaboration project of the National Institute of Information and Communications Technology (NICT) and the Japan Aerospace Exploration Agency (JAXA). JEM/SMILES observed the diurnal variation of minor species in the stratosphere and mesosphere, such as ClO, HO2, BrO, HOCl, as well as O3, H35Cl, and H37Cl.
