

Intraseasonal Predictability of Siberian High and East Asian Winter Monsoon and Its Inter-Decadal Variability

Chih-Pei Chang^{1,2} and Mong Ming Lu³

¹Naval Postgraduate School

²National Taiwan University

³Central Weather Bureau, Taiwan.

Prediction of EAWM

- Seasonal predictability
 - Most from ENSO, link to midlatitude EAWM weak (Wang et al. 2009, Kang and Kim 2011)
 - Relationship with AO/NAO mainly inter-decadal, not interannual (Gong et al. 2001, Park et al. 2011)
- Intraseasonal predictability
 - ISO identified in tropics
 - Usefulness to mid & high latitudes unclear

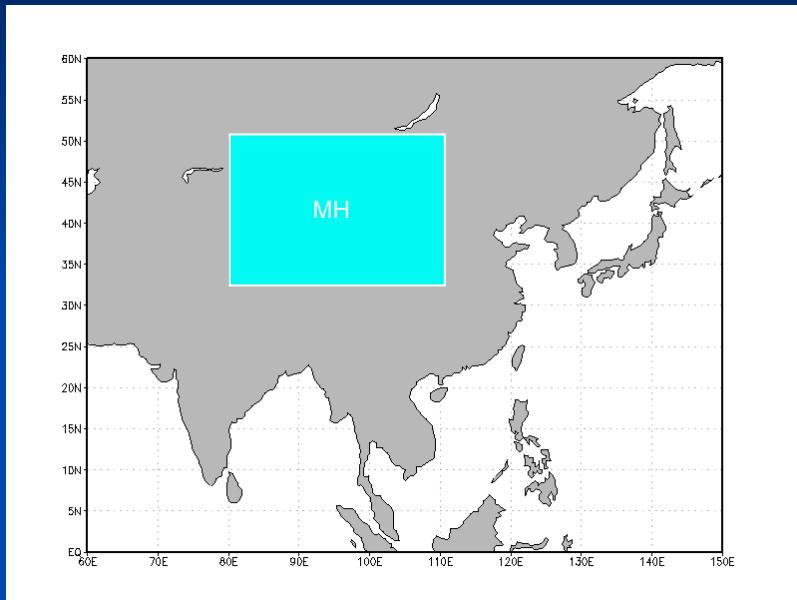

SMH (anomaly)

MH (anomaly) (1979-2008)				
corr.	Oct	Nov	Dec	Jan
OND				
NDJ				

Due to land-sea difference SMH starts to develop in fall before winter season officially sets in (Chang et al. 2004).

During this transition period, how do the rolling 3-month seasonal forecasts perform on individual months?

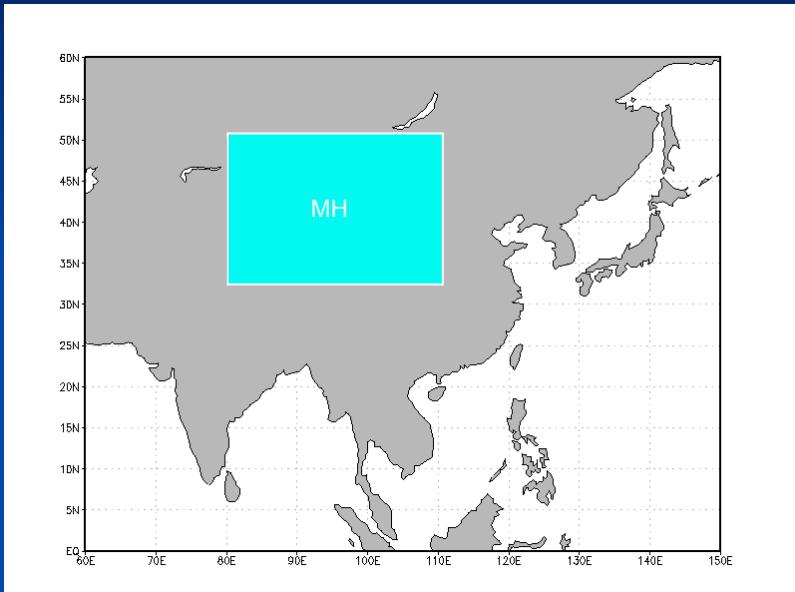

Mongolian High (MH) covering Mongolian and northern China.

Possible Mechanisms?

- ENSO - No
- Snow Cover/Depth - No
- NAO/AO - No
- AO phase?
 - Earlier decades (58-08) AO cold phase: more blocking
 - Recent decades (79-08) AO warm phase: less blocking
 - Warm phase also has lower amplitude of intra-seasonal variability (Gong and Ho 2004)
 - If blocking develops early it tends to be less likely to develop later, and vice versa?

Summary

- In 1979-2008, SH anomalies tend to change sign as the season transitions from NOV to DEC & JAN.
- Effect shows up on cold surge track from eastern China and Korea southward to southern China coast.
- Shows up as SVD2 in Nov vs Dec & Jan: SVD1 is ENSO mode, SVD2 is not related to ENSO.
- Not seen in 1959-1978 – Related in part to less frequent Pacific blocking events in the more recent decades?
- Appears to be the only major circulation system where a phase reversal can be predicted from the preceding month.
- A perfect NDJ seasonal forecast will have little use for November, and may degrade December and January forecasts.

Thank You!
