The tenth session of the JSC/CLIVAR Working Group on Coupled Modelling (WGCM) was held during 25-26 September 2006, kindly hosted by the Canadian Centre for Climate Modelling and Analysis, Climate Research Division, Canada. The session was opened at 0900 hours on 25 October by the Co-Chairs of WGCM, J. Mitchell and G. A. Meehl. A joint session with IGBP/AIMES was held on 27 September. The list of participants is given in the Appendix A to this report.

The participants were welcomed by the Co-Chairs, J. Mitchell, G. A. Meehl and V. Satyan (Joint Planning Staff, WCRP, Geneva).

On behalf of all participants, J. Mitchell expressed gratitude to Canadian Centre for Climate Modelling and Analysis, Climate Research Division, Canada, for hosting the tenth session of WGCM and the excellent arrangements made. He further expressed his appreciation to G. Flato, ably assisted by his staff, for the efforts and time they had put into the organization of the session. The Co-Chairs looked forward to the joint WGCM/AIMES session scheduled for 27 September.

1. REVIEW OF RELEVANT EVENTS IN THE WCRP AND DEVELOPMENTS IN MODELLING-RELATED ACTIVITIES

WGCM endeavours to maintain a broad overview of modelling activities in the WCRP in its basic task of building up comprehensive climate models. WGCM was informed of the main discussions at and recommendations from the twenty-seventh session of the Joint Scientific Committee (JSC) for the WCRP (March 2006) and the fourteenth session of the CLIVAR Scientific Steering Group (April 2006). In addition, updates of the recent developments within the JSC/CAS Working Group on Numerical Experimentation (WGNE), the WGCM/CLIVAR Working Group for Ocean Model Development (WGOMD), modelling activities within the WCRP core projects and the Regional Climate Modelling activities were provided.

1.1 Twenty-seventh session of the JSC

J. Mitchell briefed the session about the relevant items arising out of the twenty-seventh session of the JSC (Pune, India, 6-11 March 2006):

a) JSC thanked WGCM for the successful international workshop on analyses of climate model simulations for the IPCC AR4 convened by US CLIVAR, hosted by IPRC (Univ. of Hawaii), March 1-4, 2005 and overseen by the WGCM climate simulation panel. JSC was pleased to note that this was the largest, most comprehensive, highest profile and the most successful project ever organized by WGCM. JSC also expressed its grateful thanks to Program for Climate Model Diagnosis and Intercomparison (PCMDI) for their invaluable contribution to the collection, archival and distribution effort for the IPCC multi-model analysis activity.

b) JSC was pleased to note the great success of the WCRP/IPCC multi-model analysis activity. JSC expressed the view that synergy between WGCM and WGSIP will lead to fundamental advances in WCRP science and encouraged close collaboration. JSC would like to see more collaborative research efforts between the other projects and WGCM, particularly in connection with modelling of climate change.

c) JSC would like WGCM to lead a Pan-WCRP effort on decadal predictability as well as the development of a WCRP Task Team on ACC.

d) JSC noted that a great deal of effort is going on in various ACC activities of WCRP but that WCRP needs to raise its ACC visibility to a higher profile.

e) An initial roadmap for ACC Activity to be developed by a JSC task team recognizing the existing work of the WGCM (with contributions by the projects, groups, task teams etc) which proposes how WCRP can deliver on its objective to determine the effect of human activities on climate. (JSC Task Team Members: V. Ramaswamy (Lead), J. Mitchell, H. Le Treut, J. Marotzke; Timeline- first draft available for the next WCRP Officers, Chairs, and Directors (OCD) meeting). Terms of Reference (ToR) for this Task Team are: - With the aid of the Projects and Working Groups;
   - To document current major activities being undertaken by WCRP that relate directly to ACC
   - To identify major gaps in WCRP activities that are required to narrow uncertainties regarding ACC
   - To propose new activities that could fill these gaps and thus reduce existing uncertainties
f) JSC also encouraged holding workshops with other WCRP groups on ACC e.g. with IPCC (ETCCDI). JSC suggested that WCRP co sponsorship of ETCCDI should be ensured.

g) JSC discussed on how to deliver WCRP’s capability to the UNFCCC. JSC recommended that a Task Team should come from WGCM and other activities and be established to develop and deliver WCRP’s capability to the UNFCCC. It should have in its Terms of Reference:

- To make input to the IPCC emissions scenarios issue (now and for future mutual benefits)
- To initiate thoughtful interactions in ESSP on people/physics/bio-geochemical scenarios (ultimately perhaps the Task Team becomes an ESSP task team)
- To propose and organize world climate research for the AR5 so that results can be collected, accessed, analyzed and distributed (e.g. for impacts) (the follow-on to the “Hawaii” meeting)
- To prepare WCRP’s strategy for the final publication of AR4 in 2007 so that WCRP plans are ready and can be publicized as soon as the AR4 is officially released
- To work on the SBSTA submission, assist in preparations for the SBSTA-24 meeting (Bonn, May 2006), attend and offer a side event at Bonn and then to follow-up regularly so that each SBSTA and COP sees WCRP fully up-to-date and, if possible, endorsed by COP
- To have and continue a clear dialogue with IPCC on (i) evolving research needs (COP/UNFCCC), (ii) scenario constancy/improvement (IPCC WGs /WCRP) (iii) radiative forcing (historical improvement and analysis & modelling) (WCRP/GCOS) etc.

1.2 CLIVAR Activities

G. A. Meehl outlined the key outcomes of the CLIVAR SSG meeting held 19-22 April, 2006, in Buenos Aires, Argentina. The Co-Chairs were A. Busalacchi and T. Palmer. There are four research foci for CLIVAR: ENSO, Monsoons, Meridional Overturning Circulation (MOC)/Decadal Variability, and Anthropogenic Climate Change. There is an effort to create a CLIVAR Science Road Map with time horizons of 2007, 2010, 2013 (the latter is “sunset date” for CLIVAR). Road map elements include:

**ENSO**

- Implement (Indian Ocean) and further develop and sustain (Pacific and Atlantic) tropical ocean monitoring arrays
- Perform key planned field experiments (Tropical Atlantic Climate Experiment, Pacific and Indian Ocean process studies)
- Improve ENSO and other tropical modes of variability in coupled models in time for IPCC AR5
- Improved seasonal predictions of tropical variability, operational thermocline decadal anomaly predictions and decadal predictions with Earth System Models (ESMs)
- Paleo-ENSO with proxy data and coupled models

**Monsoons**

- GEWEX activity: “Monsoon Asian Hydro-atmospheric Scientific Research and prediction Initiative (MAHASRI) to extend CEOP-II
- Better understand and model diurnal cycle, intra-seasonal variability, and tropical mean state in monsoon regimes
- Transition from research to operations/applications
- Continue to analyze outputs from VAMOS and NAME, and continue to support AMMA
- Year of coordinated observing, modelling and forecasting of the tropics (organized convection) (YOTC), joint with THORPEX; WCRP contribution to UN International Year of Planet Earth in 2008

**Decadal variability and MOC**

- Continued and sustained monitoring of, and the identification of proxies for, the MOC
- Establish extent to which prediction is possible on decadal timescales
- Move to initialization-based approaches to decadal predictability studies
- Improved understanding of the mechanisms of decadal-interdecadal MOC variability
Anthropogenic Climate Change (ACC)

- More complex ESMs
- Understand aerosol effects, carbon cycle dynamics and cryosphere changes in terms of feedbacks (coordinate with IGBP through WGCM)
- Impact of ACC on natural modes of variability
- Pan-CLIVAR review paper related to ACC

Modeling road map elements include data assimilation for initial and boundary conditions, ensemble forecasting, improved integration of regional and global modelling, and theoretical studies on non-linear coupling between the time and space scales in the earth system. Some additional modeling elements include:

- WGSIP Seasonal Model Intercomparison project (SMIP)
- Major seasonal predication experiment under JSC Task Force for Seasonal Prediction (TFSP) (passing to WGSIP in 2007)
- Wider community involvement in WGOMD’s Coordinated Ocean-ice Reference Experiments
- Continued analysis of multi-model dataset at PCMDI

There was discussion of a CLIVAR legacy that could be “Ocean data synthesis decade” whereby the goal for a CLIVAR legacy would be to develop a global description of subsurface ocean variability and have in place a permanent and truly global ocean observation system.

CLIVAR asks WGCM: What processes do we want to see better observed as input to the panels to plan field projects?

1.3 Reports from WCRP Projects relevant to WGCM

SPARC

Chemistry-Climate Model Validation Activity (CCMVal)
(http://www.pa.op.dlr.de/CCMVal/)

The ongoing activities include

- Improvement of CCMs and their underlying GCMs through process-oriented validation
- Follow on from GRIPS (GCM-Reality Intercomparison Project for SPARC)
- Major contributions to the 2006 WMO/UNEP Scientific Assessment of Ozone Depletion
- Underpinning for the WCRP/IGBP Atmospheric Chemistry and Climate Initiative

SOLARIS (SOLAR Influence for SPARC)

The ongoing activities include

- Modelling and understanding the solar influence on climate through stratospheric chemical and dynamical processes
- Cross-cutting collaborative activity with the SCOSTEP CAWSES (Climate and Weather of the Sun-Earth System) program.
- First SOLARIS workshop will be held in Boulder CO, October 4-6, 2006.
(http://strat-www.met.fu-berlin.de/%7Ematthes/sparc/solaris.html)

Questions addressed in SOLARIS:

- What is the mechanism for solar influence on climate (dynamical and chemical response in the Middle Atmosphere (MA) and its transfer down to the Earth’s surface)?
- How do the solar cycle and QBO interact? What are the mechanisms?
- What is the spatial structure of the solar signal in ozone and temperature? To understand discrepancies between observations and model experiments.
- What is the influence of energetic particles in the Middle Atmosphere (MA) and Mesosphere & Lower Thermosphere (MLT) region?

These questions will be addressed with a set of Chemistry Climate Model (CCM) experiments (time-varying vs. perpetual solar max/min runs; multiple forcing, i.e. QBO, ENSO, volcanoes vs. solar only forcing), mechanistic model experiments and in collaboration with CAWSES a comparison with observed signals.
Atmospheric Chemistry and Climate (AC & C) Initiative

- Being led jointly by SPARC and IGAC on behalf of WCRP and IGBP.
- Initial modelling phase builds on the CCMVal experience in SPARC and takes into account that many centers have already built or are building higher resolution global models with interactive chemistry.
- Goals in this phase:
  i. defining gaps in the current representations of processes controlling chemistry-climate interactions;
  ii. assisting in filling those gaps;
  iii. defining simulations relevant to the inter-comparison of AC&C models;
  iv. defining the metrics used to evaluate the behavior of AC&C models;
  v. facilitating the inter-comparisons; and
  vi. using models to better define observational strategies.

Initial planning meeting was held during August 7-9, 2006 in Boulder, USA.

Dynamical Modelling of the Troposphere-Stratosphere System

This activity follows on from GRIPS and provides a framework for addressing a number of remaining first-order questions about GCM performance, e.g. ability to represent:

a) Polar vortices, sudden warmings and final breakdowns
b) Stratosphere-troposphere relationships and exchange
c) Tropical dynamics including key processes in the Tropical Tropopause Layer (TTL)

The activity will include a range of modelling approaches: simplified models + AMIP-style simulations with models with well resolved stratosphere (CCMVal models without active chemistry) to address a number of issues such as:

a) Characterising variability (trends in context of natural variability)
b) What is the role of the stratosphere in observed lower atmosphere variations?
c) What is the impact of stratospheric resolution and upper boundary in models on these issues?
d) Initial activity proposals to be considered at the upcoming SSG meeting (October 9-13, Boulder, CO)

GEWEX

C. Jakob presented GEWEX activities that provide a potential for the closer collaboration between WGCM and GEWEX. He pointed out that modelling efforts in GEWEX very much focus on model development through process studies while WGCM efforts are largely focused on model application and evaluation. Outlining the model development process it was shown that these two major areas of research require better links. GEWEX input into WGCM could be improved through the extensive use of GEWEX data sets in the model evaluation in WGCM and through model improvements directly targeted at climate model problems. Tropical SST biases and clouds/convection were highlighted as examples for long-standing model issues that need resolving. It was pointed out that WGCM can and should provide input into the GEWEX model development work through the setting of priorities as they arise from findings in climate and climate change simulations. The recent results of the Cloud Feedback MIP conducted under WGCM auspices are a good example for such priority setting. C. Jakob proposed a more formal close collaboration between CFMIP and GCSS. This was seen as a good initiative and C. Jakob and S. Bony have been tasked to coordinate efforts.

WCRP Observation and Analysis Panel (WOAP)

G. Flato, the WGCM representative on the WCRP Observation and Analysis Panel (WOAP), provided a brief summary of their recent meeting in Ispra, Italy (28-30 August, 2006). WOAP serves as a forum to discuss observations and data assimilation issues, to promote new observational techniques and systems, and to develop common data management activities in support of data assimilation and climate analysis. WOAP is co-sponsored by GCOS. A full meeting report is available at: http://wcrp.wmo.int/pdf/woap2_report.pdf
1.4 Reports from other WCRP modeling activities

JSC/CAS Working Group on Numerical Experimentation (WGNE)

On behalf of M. Miller, Chair of WGNE, K. E. Taylor reported on the most recent meeting of the Working Group on Numerical Experimentation (WGNE), which met jointly with the GEWEX Modelling and Prediction Panel (GMPP) in Boulder, USA, in November 2005. The report highlighted areas of mutual interest between WGNE and WGCM, and included a few items needing action from WGCM which are summarized here:

Building on its longstanding practice of monitoring and comparing model skill in forecasting weather, WGNE asked representatives of the Program for Climate Model Diagnosis and Intercomparison (PCMDI) to liaise with WGCM to develop metrics for climate models that might similarly serve the climate modeling community. WGNE set up an informal committee to promote the more routine use of metrics in the evaluation of climate modeling and invited WGCM to appoint someone as its representative on the committee.

Another common interest of both working groups is the promotion of systematic model intercomparison activities. WGNE continues to encourage the NWP centers to subject their models to the Atmospheric Model Intercomparison Project (AMIP) experiment protocol, which was established by WGNE nearly twenty years ago. Several NWP centers plan on performing AMIP experiments with their relatively high resolution models to explore the effects of higher resolution on climate simulations. At the WGNE meeting, evidence was shown that higher model resolution improved forecast skill in, for example, the prediction of the frequency of extratropical cyclones and the paths and intensity of tropical cyclones.

The increased community participation in the evaluation of climate models demonstrated by widespread interest in the CMIP3 dataset was applauded by WGNE. It recognizes the importance and value of establishing model data standards that make data from various models self-describing enough to permit common analysis of data generated by multiple models. The success of the CMIP3 effort in support of the IPCC AR4 was made possible by modeling group acceptance of the Climate and Forecast (CF) metadata standard for netCDF files. As a step toward a more uniform handling of data between NWP and climate models, WGNE indicated that it would welcome representation on the CF Governance Panel, which was expected to be appointed by WGCM.

WGCM/CLIVAR Working Group for Ocean Model Development (WGOMD)

S. Griffies presented the two main foci of the WGOMD: (i) ocean model fundamentals, and (ii) ocean climate modelling fundamentals. Ocean model fundamentals refer to elements of the model core, such as the equations being integrated, the numerical algorithms, and the subgrid scale parameterizations. There is a flurry of international activity aimed at improving the rigour of ocean model fundamentals in the process of unifying some of the previously disparate code efforts. For example, at GFDL we are merging geopotential MOM development with the isopycnal and nonhydrostatic efforts.

The resulting unified models will facilitate just as much capabilities as the previously disparate efforts, but with far less overhead spent on learning the idiosyncrasies of each different model. Furthermore, and more importantly, maintaining multiple algorithms within the same model code will greatly enhance the community's ability to rationally test the scientific utility of the various algorithms and parameterizations presently available. The present state of the art relies on different modelling groups comparing results from different model codes. This approach, unfortunately, does not allow for the careful scientifically rigorous tests required to rationally examine the various methods employed in the models.

The WGOMD aims to provide a clearing house of work ongoing in the international community focused on improving ocean model fundamentals. WGOMD has done so by writing a major review article published in Ocean Modelling (Griffies et al, 2000). This paper presented a discussion of the then state-of-the-art in ocean climate model fundamentals. WGOMD continues with this work through organizing workshops whereby various aspects of model fundamentals are explored. In particular, WGOMD is sponsoring a workshop titled “Numerical methods in ocean modelling” to be held August 23-24, 2007 in Bergen, Norway, in conjunction with the next WGOMD committee meeting.

Ocean climate modelling fundamentals refers to the experimental design of global coupled ocean and sea ice models run for centuries to millenia. Presently there is no community-wide approach to running
these models. Furthermore, details of the experimental design have nontrivial impact on the simulation integrity and sensitivity. This situation makes it nearly impossible to directly compare simulations run by different research groups, as there are too many differences, even beyond differences in model fundamentals.

The WGOMD has been working with the international community for the past five years to establish a common benchmark experimental design for global ocean and sea ice coupled models. The result of this work is a proposal known as the Coordinated Ocean-ice Reference Experiments (CORE). There are three COREs:

1. a repeating annual cycle simulation run for order 500 years aiming to highlight quasi-equilibrium simulation characteristics,
2. 50 year interannually varying simulation, aiming to explore features of the observational record,
3. a Greenland ice melt fresh water perturbation experiment that examines the sensitivity of models to fresh water melt, with the design aimed at addressing possible impacts of global warming.

Six modelling groups have participated during the past years to iterate on the experimental design and test the proposed use of the Large and Yeager (2004) dataset. This dataset was developed and continues to be supported for use in running ocean and sea ice models. A manuscript describing the CORE proposal and model simulations should be submitted early 2007.

CLIVAR Working Group on Seasonal to Interannual Prediction (WGSIP)

B. Kirtman reported on the activities of the WGSIP. Major WGSIP activities included:

1. WGSIP-TFSP interactions
   a. NWP Models Used on Seasonal Problem (THORPEX)
   b. IPCC Class Models Used on Seasonal Problem (WGCM)
   c. Decadal Predictions (WGCM)

2. Prediction Science Issues
3. Regional panel interactions

4. Planning/organizing WGSIP/TFSP seasonal prediction workshop early-mid 2007 involving SMIP2, SMIP2/HFP
5. Developing strategy and standards for seasonal prediction
6. Interaction with GEWEX - land initialization(GLACE2)
7. Scientific needs/issue for Observing System Simulation Experiments (OSSE), observing system (OSE’s) and data assimilation, coupled initialization

TFSP-WGSIP Collaboration

The Task Force on Seasonal Prediction (TFSP) was set up to coordinate and facilitate Seasonal Prediction Experiment with pan-WCRP perspective in order to provide:

--best possible treatment of all the elements of the Climate System
--assessment of skill as inputs to WGSIP and Regional Panels
WGSIP aims to provide scientific guidance, hypothesis testing, basic research (process and predictability), forecast methodology and standards, observing systems, and model improvement. WGSIP-TFSP Seasonal Prediction Experiment involves:

1. Experimental design including
   a. Coordination with ENSEMBLES and APCC
   b. Data output requirements
   c. Use IPCC Models and NWP Models

2. Data distribution strategy
3. Land initialization strategy - GLACE2
4. Impact of sea-ice on predictability (CliC)
5. Decadal Prediction
6. Seasonal prediction workshop 2007

**Prediction Science issues** address aspects such as:

- Multi-Model Prediction
- Importance of Coupled Feedbacks
- Model Errors

**WGSIP-WGCM Interactions** deal with the following:

- Testing IPCC Class Models on Seasonal-to-Interannual Prediction (with TFSP)
- Decadal Prediction and Predictability
- Atlantic Multi-Decadal Variability
- ENSO Modulation
- Tropical Biases including:
  - Mean Errors
  - Errors in Variability

### 1.5 Regional Climate Modelling

F. Giorgi presented a review of the status and recent developments in regional climate modeling and other regionalization techniques, such as variable resolution global modeling, time slice uniform resolution global modeling and statistical downscaling. The following points were highlighted:

**Regional Climate Modeling (RCMs)**

- The current target grid spacing of advanced RCMs is 10-25 km and most RCMs are being upgraded to non-hydrostatic dynamical cores. Decadal to multi-decadal simulation lengths have become the norm and some full transient centennial simulations are available.

- A number of coordinated intercomparison experiments involving multiple RCMs over different regions of the World are continuing or have been initiated (PRUDENCE, ENSEMBLES, NEWBALTIC, QUIRCS, NARCCAP, PIRCS, NAMAP, PLATIN, RMIP, AMMA, ARCMIP). Also some coordinated efforts involving multiple regions are under way, such as the Model Transferability Project and the Regional Climate research NETwork, (RegCNET).

- Interest is increasing towards the application of RCMs to seasonal climate prediction and impact assessment studies.

- Not much progress has been reported on two-way nesting after the encouraging preliminary experiments at the MPI.

- RCMs are increasingly recognised as important tools to engage developing country scientists in climate modeling research. Two modeling systems (the ICTP RegCM and the Hadley Centre PRECIS) have been developed for specific use by developing country scientists.
**Variable Resolution Atmospheric Global Modeling (VARGCM)**

- At least 4 modeling groups have developed and successfully used VARGCMs in climate and/or climate change simulations.
- The current maximum regional resolution reached by current VARGCMs is similar to that of RCMs (a few tens of km).
- One intercomparison project (SGMIP) is currently under way with 4 participating models.

**Uniform resolution time slice atmospheric global modeling (AGCM)**

- Increasingly viable technique for producing high resolution climate and climate change information.
- The current horizontal grid spacing is in the range of 20-100 km.

**Statistical Downscaling (SD)**

- Many different approaches and SD models are today available, often tied to specific applications and local conditions.
- Progress in SD is difficult to assess because of the multiplicity and diversity of approaches. Key issues appear to be the choice of suitable predictors, the availability of data for model calibration and the stationarity of the predictor-predict and relationships.
- Some coordinated projects have been carried out which have increased the understanding of uncertainties associated with SD models (STARDEX, MICE, ENSEMBLES, AIACC).

**1.6 Intergovernmental Panel on Climate Change (IPCC)**

**Fourth Assessment – update**

**Workshops**

**Task Group on Climate Impact Assessment (TGCIA)**

J. Mitchell gave a brief account of the TGCIA meeting held in South Africa, February 2006. The meeting discussed about scenarios, on back engineering from concentration scenarios, and on the quality of daily data on extreme indices that can be made available from AR4 results.

**Task Group on New Emissions Scenarios (TGNES)**

N. Nakicenovic reported on the activities of the Task Group on New Emission Scenarios (TGNES) including Integrated Scenarios in AR4 and for AR5.

**Baseline Emissions Scenarios**

- SRES scenarios are widely used for the assessment of climate change and impacts (WG1&WG2)
- WG3 has concluded, comparing new baseline emissions scenario literature with SRES (Ch 3), that:
  - there is no significant change in ranges (uncertainty) of future emissions and underlying driving forces compared to SRES
  - the main difference concerns downward correction of demographic projections (not yet implemented in the majority of new emissions scenarios)
  - the majority of the new emissions scenarios employ MER-based GDP assumptions. A few studies in the literature reporting PPP, indicate that the impact on emissions is small (problems: lack of comprehensive PPP data)
Stabilization and Mitigation Scenarios

- Major difference to TAR: studies suggest that it is technically feasible to stabilize GHG concentrations at levels significantly lower than TAR (450 CO2-eq.)
- Most of the low scenarios imply a temporal overshoot of the target
- Potential challenge for consistency – climate outcomes of these low stabilization scenarios are not analyzed in WGI (TS and SPM)
- New multi-gas literature indicates that for a specific stabilization target, emissions might peak later in time compared to TAR

TGNES Recommendations

The three IPCC WGs should use a common base:

- The assessments of impacts, adaptation and vulnerability should be consistent with views on the evolution of climate change, which in turn should be consistent with views on emissions trajectories.
- The assessment of emissions should be consistent with views of socio-economic drivers and land-use change and take account of feedbacks from climate change and response policies (e.g. stabilization)
- Finally, impacts, adaptation and vulnerability are in their turn dependent on those socio-economic drivers and land-use change.

Three options for the role of IPCC in the development of scenarios:

- B1A: Development left to the scientific community (may or may not self-organise, e.g. EMF)
- B1B: IPCC involved in facilitating (catalyzing) the establishment of a coordinating mechanism for development of new scenarios
- B2: IPCC provides coordination of scenario development

Chair Proposal on Actions of IPCC

New Task Group on Scenarios:

- Specify organization of Scenario development; what level of involvement, by whom
- Organize expert meetings in 2007: specify ‘wish list’ and ‘interagency meeting’
- Technical Paper with ‘bench mark’ emission trajectories based on AR4 in second half of 2007
- Scoping note for Special Report Integrated Scenarios (SRIS) for IPCC-26

IPCC Plenary Decision

- The Panel recognized that the development of scenarios for AR5 would be undertaken by the scientific community. The IPCC may “catalyze” such work so as to promote its readiness in time for the AR5 cycle
- Prepare a Technical Paper to summarize relevant material from the AR4 and to identify a small number of “benchmark” emission scenarios for potential use by climate modeling groups IPCC; Steering Committee to organize a meeting involving relevant communities.
- IPCC to catalyze the establishment of a coordinating mechanism (The Earth System Science Partnership: DIVERSITAS, IGBP, IHDP and WCRP)
2. NEWS FROM RELEVANT NATIONAL AND MULTINATIONAL PROJECTS

2.1 Global Modelling Activities, Japan

M. Kimoto reported on recent activities of the Japanese climate modeling community. The Ministry of Education, Culture, Sports, Science and Technology (MEXT), Japan has been promoting global warming projection studies using the Earth Simulator since 2002, under the Research Revolution 2002 (RR2002) Project, Project for Sustainable Coexistence of Human, Nature, and the Earth, in Japanese, Kyousei Project. A high-resolution AOGCM projections (by CCSR/NIES/FRCGC group), a high-resolution time slice experiment with a 20km-mesh AGCM (MRI/JMA), an overshoot scenario experiment (CRIEPI/NCAR), and development of an integrated earth system model (FRCGC/CCSR/NIES) have been successfully conducted.

The MIROC AOGCM by the CCSR/NIES/FRCGC group showed impacts of both atmosphere and ocean resolutions in an experiment with various combination of component model resolutions, the highest T213 atmosphere and 1/4 x 1/6 degree ocean. It has been noted, for this model, that the large-scale pattern of model error was not very sensitive to the resolution and the model bias was more dependent on model physics in the experiment in which most of the physics were kept unchanged. With higher resolution models, the summertime East Asian rainband, so-called Meiuy/Baiu front has been successfully reproduced and increase in heavy precipitation events under global warming has become a societal concern in Japan. The MRI/JMA 20km AGCM showed an increase in frequency of strong typhoons. The FRCGC/CCSR/NIES group has established an integrated earth system model with aerosols, stratospheric/tropospheric chemistry, and a full carbon cycle. Incorporation of a dynamic vegetation component is under way. An icosahedral global cloud resolving model is now a GCM, including land and ocean (it ran on an aqua-planet last year), although long integrations are not feasible on the Earth Simulator, which now has to cover wide-spread applications like solid earth, nano-tech, automobile, and holistic simulations.

The Kyousei project ends in March 2007, but there is a plan for upgrading the Earth Simulator, 2-5 times faster, hopefully, and another project for 10-petaflop computer is under way. A post-Kyousei project has been discussed since the beginning of 2006, an outline of which has considerable consistency with the AR5 experimental plan that has been discussed in the Aspen meeting and in this WGCM-10/AIMES meeting. Japanese community thinks it is important in the post-Kyousei program to focus on:

1. A 30-year quantitative prediction with high-resolution AOGCMs with initialization and time-slice AGCMs,
2. A 300-year projection with integrated earth system models including a full carbon cycle,
3. Quantifying and reducing uncertainties with high-resolution and physics ensembles, in the latter of which an application of ensemble Kalman filter is discussed, and
4. Projections with global cloud resolving model. The realizability of such an ambitious experiment depends on availability of the Peta-flop computer, but the use of cloud resolving simulation to test cloud parameterization is an important research subject.

2.2 Australian Community Climate and Earth System Simulator (ACCESS)

C. Jakob reported on a new Australian Initiative to build a community Earth System Model (ESM). The Australian Community Climate and Earth System Simulator (ACCESS) is a joint initiative of the Australian Bureau of Meteorology, the Commonwealth Scientific and Industrial Research Organization (CSIRO) and several Australian universities. The ACCESS mission is to build an ESM that serves as the basis for all atmosphere, ocean, biosphere and coupled prediction and simulations applications. This ranges from local/regional Numerical Weather Prediction (NWP), ocean prediction, and seasonal and intra-seasonal prediction to climate change and multi-century simulations. The components envisaged for the system are the UK Met Office data assimilation system and atmospheric model, the Australian Community Ocean (based on the GFDL MOM) and sea-ice model, the Australian community land model (CABLE) coupled with LPJ dynamic vegetation model, and the new UK Met Office Chemistry and Aerosol scheme (UKCA). All modules will be coupled using the OASIS coupler. Work on all modules is underway and it is expected that ACCESS will be making a contribution to the next IPCC assessment report.

2.3 Canadian Climate Change Model (CCCM)

G. Flato provided an update on model development at the Canadian Centre for Climate Modelling and Analysis (CCCma). He focused on development since the submission of model results to the WGCM
archive for the IPCC AR4. In particular, he described recent improvements in the ocean model component which include increased horizontal and vertical resolution, updated vertical mixing scheme, a representation of tidal mixing, anisotropic viscosity, and constriction of flow through Bering Strait. These improvements have allowed the coupled model to be run without flux adjustments. He also described progress on the representation of the carbon cycle in the CCCma model. This includes a new terrestrial ecosystem model (CTEM) and an ocean model with inorganic chemistry and ocean biology (CMOC). Initial simulations of the coupled climate/carbon system are currently underway. Finally, he described work underway on representing the sulphur cycle and simulations done with the middle atmosphere version of the CCCma model undertaken for the WMO ozone assessment.

2.4 Coupled Modelling Activities, France

P. Braconnot reported on the coupled modeling work in France. There has been much activity in France during the past years to analyse the results of the set of simulations with IPCC scenarios stored at PCMDI as part of the CMIP project. The ESCRIM project, co coordinated by IPSL and CNRM aims to use the opportunity of having two French models participating in this intercomparison, and to provide a set of analyses of these two model results to better understand model responses to increase in greenhouse gases and model differences. There are now 15 subprojects as part of ESCRIM covering a wide range of subjects, such as cloud feedback, hydrology, detection/ attribution over France, monsoon and Indian-Pacific ocean teleconnections, sea-ice evolution and ocean thermohaline circulation.

Complementary activity was also developed in each of the groups. On the IPSL side, complementary scenarios have been run with interactive carbon cycle. First simulations including a simplified version of the chemistry and aerosol model INCA should start this fall. The parallelised version of the atmospheric model is now ready and the coupled system should follow very soon. In the coming years model development will follow two different directions. The ESM version of the model includes a physical package close to the one used for AR4 simulations. Work is however going on to analyse and correct when possible known model bias. This model will serve as a basis to include the different biochemical cycles.

New developments are on the way in the different IPSL laboratories to improve model physics (clouds, diurnal cycle, boundary layer, coupling scheme, etc.). These new developments will be part of the new version of the coupled ocean-atmosphere model. Key aspects of these new developments will be fixed in the coming year.

2.5 Coupled Modelling Activities, Germany

M. Giorgetta presented the ongoing coupled modeling efforts in Germany.

**Major goal: Global Earth System Model**

- Based on existing ECHAM5/MPIOM AOGCM as used for AR4 and further components
- Carbon cycle:
  - Land vegetation model: 13 PFTs, 4 pools [dynamical vegetation in development]
  - Ocean biogeochemistry: carbon chemistry, NPZD type
- Aerosol system:
  - 7 modes
  - 5 species: dust, sea salt, sulfate, bc, part. organic matter
- Chemistry:
  - Flexible, to be configured for trop.+strat. O3
- System Integration:
  - All components + PRISM system ➔ COSMOS ESM framework

**Tested/Used ESM configurations**

- AOGCM (= dynamic physical core) (IPCC AR4)
  - Troposphere, ptop=10hPa, L31 (IPCC AR4)
  - Middle atmosphere, ptop=0.01 hPa, L47
Carbon cycle model (experimental AR4)
- Aerosol system model (experimental AR4)

**Tested/Used ESM chemistry atmosphere models**

- Atmosphere + troposphere chemistry (2x)
- Atmosphere + troposphere chemistry + aerosol
- Whole atmosphere model incl. chem. (SOLARIS)

\[ \rightarrow \text{AR5: Integrate CC, aerosols, simple/cheap O3 chemistry} \]

**Development lines beyond AR5: ICON models, (collaboration with DWD)**

- Basic Properties:
  - Icosahedral grids
  - Optional local grid refinement
  - Global or regional domain
  - Hydrostatic or non-hydrostatic
  - Atmosphere and ocean model

- Current status:
  - Shallow water model (completed)
  - Hydrostatic dyn. core (first tests)

**Other coupled model efforts in Germany:**

- Mojib Latif, IFM GEOMAR
  - ECHAM5/OPA

2.6 **Geophysical Fluid Dynamics Laboratory (GFDL), USA**

T. Delworth reported on the GFDL Climate Modeling activities:

- The current “workhorse” model is version CM2.1 (ATM: 2 degree, 24 levels; OCN: 1 degree, 50 levels, model used for full suite of IPCC AR4 runs)
- Recent activity is aimed to create a “roadmap” to ESM3/CM3 (AR5 model)
- Key emphasis is on Earth System Model
- Current plan is to have model “ready” by January, 2009

**GFDL “Roadmap” to ESM3/CM3**

- One constraint: modest computational resources

- Three streams of approach – computational resources and model maturity will dictate which stream is main model. Streams differ in resolution:
  - Atmosphere: 2 degree, 48 levels Ocean: 1 degree, 50 levels
  - Atmosphere: 1 degree, 48 levels Ocean: 1 degree, 50 levels
  - Atmosphere: 1 degree, 48 levels Ocean: 1/4 degree, 50 levels

- Atmospheric physics/numerics changes under development:
  - Improved resolution in stratosphere
  - Trop/strat interactive chemistry
  - Convection, boundary layer, gravity wave drag
  - Indirect aerosol effect
  - Cubed-sphere grid

- Ocean directions
  - Physics/numerics changes from ocean component of CM2.1. These include:
    a. Higher order advection (Prather)
    b. Smagorinsky biharmonic viscosity
    c. Enhanced tidal mixing, no Bryan-Lewis diffusivity -CM2.1.1
- Hallberg isopycnal model – has been successfully coupled to AM2.1 atmosphere - CM2.2
- New ocean code under formulation – GUOM (GFDL Unified Ocean Model)

- Land model directions:
  - Far more comprehensive soil water treatment - Chris Milly, USGS
  - Much improved river routing and dynamics – Kirsten Findell, GFDL
  - Terrestrial carbon cycle – Elena Shevliakova, Sergey Malyshev

**GFDL’s current Earth System Model for coupled carbon-climate studies** (courtesy John Dunne)

- Coupled physical model (CM2.1):
  - AM2 atmosphere finite volume grid (2° horizontal, 24 levels)
  - MOM4 ocean model, 1° horizontal, 0.3° at Equator, 50 levels)
  - Dynamic sea ice (SIS)
  - Dynamic land radiation and bucket hydrology with river routing (LM2)

- Terrestrial vegetation (LM3v):
  - Carbon in leaves, sapwood, wood, fine roots, and 2 soil pools
  - Dynamic succession of vegetation types between tropical evergreen, coniferous evergreen, temperate deciduous, warm grasses (C4) and cold grass (C3)
  - Land use with pasture, crops, and secondary forestry (years 1700-2000)
  - Annual fire losses
  - Dynamic sub-gridscale heterogeneity

- Ocean ecology and biogeochemistry (GOB):
  - Coupled elemental cycles of C, N, P, Si, Fe, O₂ and alkalinity and lithogenic material
  - 3 Phytoplankton functional groups with co-limitation, flexible physiology and size-based grazing
  - Size-based detritus formation and mineral protection during sinking
  - 3 dissolved organic matter components
  - Solubility-based CaCO₃ sedimentation and dissolution
  - N₂-fixation and denitrification in sediments and the water column
  - Air-Sea gas exchange, atmospheric deposition, and runoff of C, N, Fe, O₂, alkalinity and lithogenic material

2.7 National Center for Atmospheric Research (NCAR), USA

G. A. Meehl reported on the global coupled climate model efforts at NCAR which are coordinated nationally through the Community Climate System Model (CCSM) project in partnership with NCAR, universities and some government laboratories. Ten working groups coordinate research and model development, and address: atmosphere, ocean, polar, land surface, biogeochemistry, climate change, climate variability, software engineering, paleoclimate, and chemistry.

**Currently active climate models at NCAR:**

1. Parallel Climate Model (PCM; still runs, but nearing retirement): atmosphere: CCM3.2, T42, 18L; ocean: POP, 2/3 to 1/2 degree in eq. Tropics, 32L, biharmonic diffusion, Pacanowski/Philander mixing; sea ice: dynamic (EVP), thermodynamic; and land surface: LSM.

2. Community Climate System Model version 2 (CCSM2; limited runs mainly with water hosing experiments and closed/open Bering Strait experiments): atmosphere: CAM2, T42, 26L; ocean: POP, 1 to 1/2 degree in eq. Tropics, 40L, GM, KPP; sea ice: dynamic (EVP), thermodynamic; and land: CLM.

3. CCSM3 (main workhorse model, actively being run for black carbon-only, anthropogenic vs. natural forcings for 20th century, tropical thermista low resolution run for paleoclimate experiments): atmosphere: CAM3, T85, 26L (also T31 and T42); ocean: POP, 1 to 1/2 degree in eq. Tropics, 40L, GM, KPP; sea ice: dynamic (EVP), thermodynamic, land: CLM.
4. **WACCM** (run for atmospheric chemistry experiments, stratosphere/troposphere interaction, solar influences, etc.): finite volume dynamical core, many more levels in the stratosphere, and coupled chemistry (not coupled to ocean yet).

5. CSM1 with carbon cycle (currently running AOGCM with coupled carbon cycle): CAM1 atmosphere, T31, 3 degree ocean, terrestrial and ocean carbon cycle

6. Prototype CCSM4: atmosphere: CAM4, finite volume, (1 degree and 2 degree versions), POP, 1 to 1/2 degree in eq. Tropics, 40L, GM, KPP; sea ice: dynamic (EVP), MOZART chemistry, terrestrial and ocean carbon cycle (and ocean ecosystem model), dynamic vegetation, sulfate indirect, mineral dust, other aerosols (GHAN scheme).

3. **REVIEW OF WGCM INITIATIVES**

3.1 **Coupled Model Intercomparison Project (CMIP)**

G. A. Meehl presented an update on CMIP. Significant accomplishments related to CMIP during the past year are:

- PCMDI has collected, archived and distributed the model data (and will do so for next few years); the WGCM Climate Simulation Panel (Members: G.A. Meehl, J.F. Mitchell, McAvaney, M. Latif, C. Covey, R. Stouffer), set up by WGCM, has overseen and coordinated collection, archival, and analysis of model data for the IPCC AR4; over 683 scientists have registered to analyze the IPCC model data; well over 200 papers submitted to peer-reviewed journals, and 177 have been published so far.

- Coupled Model Evaluation Project (CMEP) to address drought proposed through US CLIVAR (July, 2006)

- Catalogue of MIPs maintained with cooperation of WGCM and AIMES, and is maintained on WCRP web page with link from CMIP web page

- CMIP has produced significant contributions to IPCC AR4; There are 43 CMIP2+ subprojects currently active, in addition to 10 completed subprojects from CMIP1 and 22 from CMIP2; 683 active projects now involve the multi-model dataset as CMIP has been encompassed in that larger dataset/effort.

- Announcement soliciting modeling groups to submit natural and anthropogenic forcing 20th century simulations sent out in August, 2006 (contact person: D. Karoly)

- Aspen Global Change summer session (August, 2006) organized to address next generation earth system models and propose a strategy for an experimental design for coordinated experiments for IPCC AR5.

G.A. Meehl has been the chairman of CMIP since its inception in 1995. During that time there have been several stages of CMIP (CMIP1, CMIP2, CMIP2+, and most recently CMIP3). The latter, CMIP3, was an unprecedented effort to coordinate the international modeling groups to run a set of 20th and 21st century climate change experiments, in addition to several climate change commitment experiments. Output from these experiments was collected and archived at PCMDI, and CMIP then organized an ambitious international model analysis activity that made major contributions to the IPCC AR4. So far over 170 papers have been published out of the well over 200 papers that have been written as outcomes of this activity. This level of scientific productivity as a direct consequence of CMIP3 has far exceeded even our most optimistic projections when we initiated the project. Thus CMIP has brought global coupled climate model intercomparison and analysis to an internationally coordinated level never before achieved in the field of climate science. As we begin to contemplate a strategy for earth system model experiments and analysis for a possible IPCC AR5, G.A. Meehl has decided to step down as chairman of CMIP and R. Stouffer (a CMIP Panel member since its inception) has agreed to become the new CMIP chairman. Additionally, C. Covey (another original CMIP Panel member) has agreed to become CMIP vice-chair. G.A. Meehl will stay on as a
CMIP Panel member in addition to his duties as co-chair of WGCM. He would like to thank the CMIP Panel members for their dedication and support over the years for this very worthwhile activity, and he wishes R. Stouffer and C. Covey the very best as they lead upcoming CMIP activities related to earth system models.

3.2 International Cloud Feedback Model Intercomparison Project (CFMIP)/Idealized experiments

S. Bony reported on the activities of the first phase of CFMIP (set up in 2003 by B. McAvaney and H. LeTreut) as well as its outcome in terms of publications and of participation in the IPCC AR4 (cf: http://www.cfmip.net for more information) including an overview of the current assessment on cloud-climate feedbacks. The main conclusions were that (1) cloud feedbacks remain the largest source of uncertainty for equilibrium climate sensitivity estimates, the spread in cloud feedbacks leading to inter-model differences of roughly a factor of 2 among models, and that (2) thanks to recent model intercomparisons of cloud feedbacks (within the framework of CMIP and CFMIP), and to the development of new methodologies of analysis of cloud feedbacks, low-cloud cover has now been pointed out as a primary culprit of this spread. This shows that model comparisons of cloud feedbacks are useful to identify primary sources of uncertainty in climate models, and provide guidance for future observational and process studies (e.g. for GEWEX/GCSS). However, to date we are still unable to determine which of the model cloud feedbacks are the more reliable, which would be necessary to narrow the uncertainty in climate sensitivity estimates.

Preparations for the second phase of CFMIP (CFMIP2) are ongoing. The main objective of CFMIP (which is now under new management) will be to allow for a better assessment of climate change cloud feedbacks for the AR5. This requires progress in three different areas:

- the evaluation of cloud fields,
- the understanding of climate change cloud feedbacks in climate models and of intermodel differences in cloud feedbacks,
- our ability to determine which of the climate change cloud feedbacks seem the more reliable based on our physical understanding of cloud feedbacks and on the ensemble of evaluation tests applied to models' clouds.

The aim of CFMIP2 is to encourage research in these 3 areas, to develop and to distribute tools that may be helpful for this purpose, and to strengthen the interaction between WGCM and other "cloud" communities, particularly GEWEX (GCSS, GRP).

Specific plans and initiatives of CFMIP2 are:

- To improve the evaluation of cloud fields in climate models, we think that both process-level evaluations as well as large-scale evaluations should be performed. Process-level evaluations should be encouraged by interacting more with GCSS (see below). To improve the evaluation of clouds from space observations, we plan to develop and to distribute to the GCM community a CFMIP CloudSat/CALIPSO Simulator (C3S) to simulate lidar and radar signals from model variables. By comparing these simulated signals to the new CloudSat (radar) and CALIPSO (lidar) data, it will be possible to evaluate the model cloud properties (including their vertical structure) in much more detail. We propose to make the use of this simulator become part of IPCC requirements for the AR5 simulations.

- To improve our understanding of climate change cloud feedbacks, we wish to encourage the analysis of cloud feedbacks by a wider community. For this purpose, we wish to make available to the whole community (e.g. through the CMIP3 database at PCMDI) as much cloud diagnostics as possible (including daily data from CFMIP1).

- To determine how we might determine which of the climate change cloud feedbacks are the more reliable based on physical understanding of the feedbacks and observational tests, we need to develop new methodologies. This issue will be addressed during CFMIP/ENSEMBLES workshop to be held in Paris on April 2007.

Recommendations / Actions:

It has been proposed that:

- WGCM may endorse the CFMIP2 project by March 2007.
- using the ISCCP simulator (and eventually the combined ISCCP/radar/lidar simulator if available) in climate models should become an IPCC requirement for the AR5.
- in the future, CFMIP may have "two parents": WGCM and GEWEX. Interactions with C. Jakob on this issue will take place over the next few weeks.

3.3 Model initialization and forcing scenarios

R. Stouffer reported on this topic. The process of designing the common experiments for AR5 is starting. A white paper detailing the reasoning for the proposed experiments is available. Two sets of integrations are proposed. One is a short term forecast to address the topics of atmospheric chemistry, decadal predictability and regional climate change. The second experiment closes the carbon cycle and investigates the impact of climate change on the carbon cycle and the feedbacks.

The short term experiment will start from observed initial conditions (all components) near present day. The integrations will be several decades in length and use atmospheric models with resolutions around ½ to 1 degree, possibly with model tops above the stratosphere. The atmospheric models will include chemistry modules. In addition to the climate response, air quality issues will also be investigated.

The longer term experiment is similar in design to the AR4 integrations in the multi-model database at PCMDI. Concentrations of GHG and aerosols will be used to force the models. The model resolution and integration lengths will be similar to the AR4 models. Fluxes of carbon will be archived and used to investigate the impact and feedback of including the carbon cycle.

3.4 Climate Change Detection, ETCCD

D. Karoly reported on the activities of the Expert Team on Climate Change Detection (ETCCD).

The main points were:
- Major involvement in IPCC WGI Chapter 9 and WGII Chapter 1.
- Request to modelling groups to add ANTHROP and NATURAL only forcing runs for 20C3M to MMD at PCMDI.
- Official link with WMO CCI/CLIVAR/JCOMM Expert Team on Climate Change Detection and Indices (ETCCDI). ETCCD was reformed in 2006 for an additional 3 year term and will meet in Canada in November 2006.
- ETCCD has unofficial link with IDAG (International Ad hoc Detection and Attribution Group) jointly funded by DoE and NOAA in US. It has secured new funding for an additional 3 years in 2006. The group will meet in March 2007 in US and the emphasis will be on regional attribution and on extremes.

3.5 Palaeoclimate modelling

P. Braconnot reported on this agenda item. The paleoclimate intercomparison project is now in its second phase. Simulations of the Last Glacial maximum (LGM, 21ka BP) and of the mid-Holocene (6ka BP) are two key benchmarking periods for this project for which several modelling groups ran similar simulations that are stored in a common database at LSCE (France). Several papers analysing these simulations were published or were submitted. Some of them, concerning polar amplification, the comparison of LGM model results with proxy data over North Atlantic and the Eurasian continent, served as a basis for the IPCC AR4 assessment. Other studies concerning tropical cooling and deep ocean circulation are on the way. New results in this second phase concern the analyses of interannual variability and climate sensitivity. Several groups started to analyse changes in ENSO during mid-Holocene and LGM. Published data reconstructions using coral data, tree rings, varved layers in lakes, suggest that the east Pacific was colder with less interannual variability whereas sites to the North of Australia are wetter. These indications show that there was less ENSO variability and suggest larger tilt of the east–west SST gradient across the equatorial Pacific Ocean. Previous studies using the Zebiak and Cane model reported that the increased SST gradient during mid-Holocene triggers the Berknes feedback (Clement et al. 1999), decreasing the ENSO activity and favouring a Niña state. Nearly all PMIP simulations of the mid-Holocene produce reduced ENSO variability. It is however difficult to relate this to changes in the SST gradient. A better relationship is found with enhanced trade winds in west Pacific induced by the late retreat of the Asian JJA monsoon. Simulations of
the LGM climate do not produce such a consistent response between different models, more in the light of what is going on with future climate experiments. Several new studies have appeared also in the literature trying to use information from LGM data to constrain climate sensitivity. These studies differ by the complexity of the models used, the set of parameters that are varied in the climate models, and the assumption made on model errors. They consider that there is a reasonable relationship between tropical cooling at LGM and future climate sensitivity. The possibility of using LGM to better constrain climate sensitivity also started using PMIP2 simulations. Results show Antarctic regions are well suited to provide an answer and that there is also a tight relationship between tropical ocean cooling and climate sensitivity. There is however still a limited number of LGM simulations in PMIP2 data base and more groups are welcome to join and produce those simulations.

3.6 Decadal Variability

T. Delworth reported on decadal variability and predictability. Some of the key issues involved are:

Atlantic variability and hurricanes

- Controversy about the relative roles of natural variability and forced climate change for recent increases in Atlantic hurricanes.

- Mann and Emmanuel (2006), Trenberth and Shea (2006) suggest little (if any) role for internal variability.

- If true, this has substantial implications for future projections of hurricane activity.

Role of Atlantic in modulating Pacific/ENSO.

- Warm North Atlantic leads to weak ENSO variability (Dong et al., 2006). The causal chain for this relationship is as follows: Warm North Atlantic $\rightarrow$ Caribbean Low $\rightarrow$ Enhanced Tropical Pacific Westerlies $\rightarrow$ More stratified eastern tropical Pacific $\rightarrow$ weaker ENSO

Impact of Pacific on North American droughts

- Growing support for influence of a particular pattern of (mainly) Pacific SST anomalies on North American drought (Seager et al., Schubert et al.)

- Interaction between Pacific and Atlantic SST anomalies for North American drought. Pacific and Atlantic SST anomalies are seen to be associated with major North American droughts. A common feature is the cool central and eastern tropical Pacific. Some Atlantic influence is also seen.

- Is there any predictability?

Decadal predictability

Several studies (from Griffies et al, 1997, to Latif et al, 2006) have documented decadal scale predictability of the MOC in the Atlantic as deduced from coupled ocean-atmosphere models. Not as much decadal predictability has been shown in the Pacific. This decadal predictability is one of the key underpinnings for the drive to initialize coupled climate models from observed state of the ocean.

Key Issues:

a) How much impact is there for continental climate? Results to date are mixed, even in perfect predictability experiments.

b) Does this translate into predictability of atmospheric circulation of climatic relevance (i.e., tropical conditions relevant to hurricanes; Pacific SST patterns of relevance for North American drought)?

c) Are our current models a fair evaluation of the actual predictability in the system?

   i. Are our models good enough?
   ii. Do model atmospheres interact with the ocean realistically?
   iii. Are we missing inherent types of oceanic variability?
4.0 OTHER ACTIVITIES

4.1 Carbon Cycle modelling & the Coupled Carbon Cycle Climate Model Intercomparison Project (C4MIP)

C4MIP

C. Le Quéré reported on the activities of the C4MIP. The Phase 1 of C4MIP intended to compare forced simulations over the historical period. This phase was temporarily abandoned because of the lack of time and the pressure to go ahead with Phase 2 and do fully coupled simulations. Phase 2 is now finished. One summary publication came out in Climate Dynamics (Friedlingstein et al, 2006). Most groups also published their own model results. Planning for Phase 3 was supposed to take place during a strategy meeting in Exeter in October 2006. C. Jones is to propose simple scenarios to allow a better analysis of the feedbacks.

There are both scientific and technical problems related to this exercise. The scientific problems are first that we only have a fragmented understanding of some of the processes, second that there are only limited observations for validation, and finally that since the models are incomplete (e.g. no fires, no land use), they should not be expected to reproduce observations, which makes validation very difficult. The technical problems are that there is no financial support for C4MIP activities, there are currently no standards, 3D fields are not shared, and there is no archiving strategy.

Ongoing model developments:

On land, most groups are working on including a representation of fires, land use, the methane and nitrogen cycles, and advanced ecosystem dynamics (including competition and succession). The unresolved issues include uncertainties regarding the importance of CO₂ fertilization, forest re-growth, temperature dependence of soil respiration, and the balance of the methane budget.

In the ocean, most groups are working on including more advanced ecosystem dynamics (incl. grazers and multiple Plankton Functional Types), flexible nutrient ratios and quota models. Some groups are working on a global representation of the coastal ocean and on links with higher tropic levels. The observations are in much better shape in the ocean, with breakthroughs this year on the detection of Plankton Functional Types from satellite data, and on the analysis of decades of pCO₂ data from ship surveys. The unresolved issues are that we still do not know if marine ecosystems can have a significant impact on CO₂ fluxes and other gases in the decades to come.

4.2 Data Management Issues

The recent WGCM CMIP3 activity, which made available an unprecedented amount of model output for widespread community scrutiny and was heavily relied upon in the preparation of the IPCC’s Fourth Assessment report (AR4), demonstrated the value of establishing standards for the dissemination of model data. K. E. Taylor summarized some of the ingredients to the success of CMIP3 and also brought up shortcomings of the present approach and issues of relevance to future exercises of this kind.

The benefits and importance of the Climate and Forecast metadata standard (CF), which is increasingly being adopted by a variety of model intercomparison projects, was stressed as a critical element in making CMIP3 successful. Although CF evolved largely as a grass-roots effort relying on voluntary contributions, the originators of the standard are now seeking a more permanent steward. The active members of the CF community see the WGCM as the rightful home for CF. In a white paper presented to the WGCM (http://cf-pcmdi.llnl.gov/future_of_cf_final), a governance structure is proposed in which a panel appointed by WGCM would assume responsibility to 1) promote integration of CF across WCRP programs and encourage its appropriate use, 2) provide for CF continuity into the future by, for example, seeking organizations to voluntarily provide for the maintenance of CF should the currently support at the British Atmospheric Data Centre and the Program for Climate Model Diagnosis and Intercomparison (PCMDI) falter, and 3) formally appoint volunteers to serve on the two working committees: the Convention Committee and
the Standard Name Committee. The WGCM expressed support for CF and asked K. E. Taylor to provide a list of nominations for the CF Governance Panel.

In planning for future model intercomparison activities, a number of issues were presented. Some of these involved technical extensions needed to CF. Plans were discussed for improvements to services associated with the CMIP3 database (e.g., improved notification of changes to the database, improved sub-setting capability, and more complete documentation of models and experiments in the database. The importance of establishing benchmark experiments, such as AMIP and the CMIP control, 20th century, and 1%/year CO2 increase simulations, was emphasized as it allows quantification of evolving changes in model performance. Finally, plans for a potential Fifth Assessment Report by the IPCC are being made by PCMDI. Among the issues that are being addressed are 1) modifications to the list of standard output in response to needs of the "impacts" community and the inclusion of Earth System Model simulations, 2) less centralized storage of data and the development of a federated distributed dataset, and 3) accommodation of data on non-rectilinear grids.

5. INTERACTIONS WITH OTHER PROGRAMMES

5.1 Global Carbon Project (GCP):

C. Le Quéré also reported on the activities of the ESSP/Global Carbon Project. The GCP is fostering several activities on:

- the vulnerability of CO2 sinks. The general goal is to quantify the size of the pools, identify their location, understand key processes leading to the destabilization of the pools, and to quantify the potential CO2 release over this century. A synthesis is planned for 2008-09. The specific activities include the vulnerability of (1) fires and droughts, which are sensitive to water stress and vegetation change, and are affected by the interannual variability in extremes, (2) tropical peat-lands, which are sensitive to warming, land use practices, and fires, (3) permafrost, which is sensitive to warming, (4) air-sea CO2 fluxes, which are sensitive to changes in ocean physics and warming, marine ecosystems response to warming, pH, changes in nutrient and light availability, (5) methane hydrates, which are sensitive to warming and pressure, (6) coastal CO2 fluxes, which are sensitive to warming, nutrient input, and change in water flow. Activities on other wetlands and peat-lands are not yet organized,

- annual CO2 budget. The GCP has committed to publish CO2 budgets around the month of July each year. The analysis of the budgets for up to 2005 is submitted for publication,

- regional carbon budgets (particularly China) and projects on carbon and water issues in Asia,

- carbon management at the urban and regional levels. A conference took place in Mexico in September on connecting development decisions to global issues,

- defining guidelines for offsetting your carbon emissions (coming this year).

General issues regarding modeling of the carbon cycle: The estimated feedbacks between the carbon cycle and both climate and CO2 will probably increase some more before they can be constrained. Thus it is possible that the projections of temperature range from climate models simulations increases. Some separation of the range caused by the c-cycle feedbacks (which are poorly constrained) from that caused by the uncertainties in climate modeling may be appropriate. The feedback with climate is strongly dependent on the water cycle.

6. ADMINISTRATIVE MATTERS

6.1 Membership

The JSC at its XXVII session in March 2006, considered the proposals submitted by the WGCM Co-chairs for the memberships of the group. The terms of Drs P. Braconnot and A. Hirst, which expired on 31 December 2005, were each extended by two years. Dr S. Griffies (GFDL, USA), Ex-officio, Chair of WGOMD replaced Dr C. Boening who stepped down as Co-Chair, WGOMD. The term of Dr T. Delworth, which was due to expire on 31 December 2006, was extended by three years. Dr B. McAvaney stepped down at the end of his term on 31 December 2005. Dr N. Nakicenovic, IIASA and Vienna University of Technology, Austria, was appointed a new member of the group for an initial term of four years, effective 1 January 2006. The group was thus constituted as follows:
7. **DATE AND PLACE OF THE ELEVENTH SESSION OF WGCM**

At the kind invitation of Dr M.A. Giorgetta, Max Planck Institute for Meteorology, Germany, the next session of WGCM, the eleventh, would be held at Hamburg, Germany, 3-5 September 2007.

8. **CLOSURE OF THE SESSION**

The participants expressed their thanks to the local organizer Dr G. Flato and to the staff of the Canadian Centre for Climate Modelling and Analysis, Climate Research Division, Canada, for hosting this session, for the excellent arrangements made and the facilities and hospitality offered. The tenth session of WGCM was closed at 18.00 hours on 26 September 2006.

9. **WGCM-AIMES JOINT SESSION**

The WGCM-AIMES joint session was opened by J. Mitchell and D. Schimel, Co-Chairs of WGCM and AIMES respectively, at 0845 hrs on 27 September. The Co-Chairs outlined the aim and scope of the joint session. The agenda for session essentially centred on the joint WGCM-AIMES Workshop held during July 30-August 5, 2006, at Aspen, Colorado, USA. The agenda included (i) overview/summary of Aspen Workshop, (ii) modelling group responses to survey regarding near-future modelling plans, and (iii) discussion to formulate conclusions for the white paper. The session included presentations and discussions led by J. F. Mitchell, D. Schimel and G.A. Meehl. In his introduction, J. F. Mitchell referred to the new scenarios and issues connected with them such as: (i) loss of continuity, (ii) extra work with little scientific benefit, (iii) political issues, and (iv) fragility of socioeconomic assumptions, and outlined the new approach to the scenarios. D. Schimel stressed the complexity of the problem involved in dealing with the Earth System Models and the special responsibility carried by the two groups which included: (i) taking control of the processes and dealing with the scientific uncertainties, (ii) issues of the 21st century, and (iii) policy imperatives. Major topics discussed included: (i) the next generation earth System Models, (ii) the modeling data archives at PCMDI and Hamburg, (iii) the near term experimental designs(2005-2030), the long term experimental designs( 2100 and beyond), (iv) recommendations from the Workshop and (v) the next steps including development of a white paper and recommendation to IPCC. The white paper has since then been prepared: See Appendix D: “A Strategy for Climate Change Stabilization Experiments with AOGCMs and ESMs – Report from Aspen Global Change Institute session, July 30-August 5, 2006 and joint WGCM/AIMES Steering Committee Meeting 27 September, 2006 by G. A. Meehl and K.Hibbard”. This is also available at [http://wcrp.wmo.int/documents/Aspen_WhitePaper_1final_000.pdf](http://wcrp.wmo.int/documents/Aspen_WhitePaper_1final_000.pdf)
APPENDIX A

List of participants at the WGCM-10 meeting
(Victoria, BC, Canada, 25-27 September 2006)

WGCM Members

DR S. BONY-LENA
Laboratoire de Météorologie Dynamique (LMD/IPSL)
CNRS/UPMC
Tour 45-55, Case 99
4 place Jussieu
F-75252 Paris Cedex 05
FRANCE
Tel: (+33-1-44-27-50-14)
Fax: (+33-1-44-27-62-72)
Email: bony@lmd.jussieu.fr

DR P. BRACONNOT
Laboratoire des Sciences du Climat et de l'Environnement
Unité mixte CEA-CNRS
Orme des Merisiers, Bat. 712, CE-SACLAY
F-91191 Gif-sur-Yvette Cedex
FRANCE
Tel: (+33-1-69-08-77-21)
Fax: (+33-1-69-08-77-16)
Email: Pascale.Braconnot@cea.fr

DR T. DELWORTH
Geophysical Fluid Dynamics Laboratory
Princeton University
P.O. Box 308
Princeton, NJ 08542
UNITED STATES OF AMERICA
Tel: (+1-609-452-6565)
Fax: (+1-609-987-5063)
Email: tom.delworth@noaa.gov

DR G. FLATO
Canadian Centre for Climate Modelling and Analysis
Meteorological Service of Canada (MSC)
University of Victoria
Canadian Centre for Climate Modelling and Analysis
P.O. Box 1700
Victoria, BC V8W 2Y2
CANADA
Tel: (+1-250-363-8223)
Fax: (+1-250-363-8247)
Email: greg.flato@ec.gc.ca

DR M. GIORGETTA
Max Planck Institute for Meteorology
Bundesstrasse 53
D-20146 Hamburg
GERMANY
Tel: (+49-40-41173-358)
Fax: (+49-40-41173-298)
Email: giorgetta@dkrz.de

DR F. GIORGI
International Centre for Theoretical Physics (ICTP)
Physics of Weather and Climate Section
P.O. BOX 586, Strada Costiera 11
I-34100 Trieste
ITALY
Tel: (+39-040-2240-425)
Fax: (+39-040-2240-449)
Email: giorgi@ictp.trieste.it

DR S.M. GRIFFIES
Geophysical Fluid Dynamics Laboratory
Princeton Forrestal Campus Rte. 1
201 Forrestal Road
Princeton, NJ 08542-0308
USA
Tel: (+1-609-452-6672)
Fax: (+1-609-987-5063)
Email: stephen.griffies@noaa.gov
http://www.gfdl.noaa.gov/~smg
DR D. KAROLY  
Williams Chair and Professor of Meteorology  
University of Oklahoma  
School of Meteorology  
100 E. Boyd Street  
Norman, OK 73019  
UNITED STATES OF AMERICA  
Tel: (+1-405-325-6446)  
Fax: (+1-405-325-7689)  
Email: dkaroly@ou.edu

PROFESSOR M. KIMOTO  
University of Tokyo  
Centre for Climate System Research (CCSR)  
5-1-5 Kashiwanoha, Kashiwa-Shi  
Chiba 277-8568  
JAPAN  
Tel: (+81-04-7136-4385)  
Fax: (+81-04-7136-4375)  
Email: kimoto@ccsr.u-tokyo.ac.jp

DR C. LE QUÉRÉ  
University of East Anglia/ British Antarctic Survey  
School of Environmental Sciences  
Norwich NR4 7TJ  
UNITED KINGDOM  
Tel: (+44-1603-592840)  
Fax: (------------------)  
Email: c.lequere@uea.ac.uk

Dr G.A. MEEHL  
National Center for Atmospheric Research (NCAR)  
Climate and Global Dynamics Division  
P.O. Box 3000  
Boulder, CO 80307-3000  
USA  
Tel: (+1-303-497-1331)  
Fax: (+1-303-497-1333)  
Email: meehl@ncar.ucar.edu

PROFESSOR J. MITCHELL  
Met Office  
Fitzroy Road  
Exeter EX1 3PB  
UK  
Tel: (+44-1392-884604)  
Fax: (+44-1392-884400)  
Email: john.f.mitchell@metoffice.gov.uk

PROFESSOR N. NAKICENOVIC  
Professor of Energy Economics  
| Leader Transitions to New Technologies  
| Power Systems and Energy Economics  
| and Greenhouse Gas Initiative  
Vienna University of Technology  
| International Institute for  
Gusshausstrasse 25-29/37320  
Applied Systems Analysis (IIASA)  
A-1040 Vienna,  
Austria | A-2361 Laxenburg,  
Austria  
Tel: (+43 1 58801 37350)  
Fax: (+43 2236 807 411)  
Fax: (+43 1 58801 37397)  
Fax: (+43 2236 807 488)  
Email: naki@eeg.tuwien.ac.at  
Email: naki@iiasa.ac.at

Unable to attend

DR T. HIRST  
CSIRO Atmospheric Research  
PMB 1  
Aspendale, Victoria 3195  
AUSTRALIA  
Tel: (+61-3-9239-4531)  
Fax: (+61-3-9239-4444)  
Email: tony.hirst@csiro.au
Other Invitees

DR D. BADER  
Director, PCMDI  
Lawrence Livermore National Laboratory  
P.O. Box 808, L-103  
Livermore, CA 94550  
USA  
Tel: (+1-925-422-4843)  
Fax: (+1-925-422-7675)  
Email: bader2@llnl.gov

DR H. CATTLE  
Director, International CLIVAR Project Office  
National Oceanography Centre  
Empress Dock  
Southampton SO14 3ZH  
UNITED KINGDOM  
Tel: (+44-2380-596208)  
Fax: (+44-2380-596204)  
Email: hyc@noc.soton.ac.uk

DR C. COVEY  
PCMDI  
Lawrence Livermore National Laboratory  
P.O. Box 808, L-103  
Livermore, CA 94550

Tenth session of the JSC/CLIVAR Working Group on Coupled Modelling (WGCM)
Victoria, BC, Canada, 25-26 September 2006

AGENDA

DAY 1  Monday, September 25

0900-0915  Welcome  -J. Mitchell, G. Meehl, G. Flato
Introductions
Times, local arrangements
Adoption of the agenda

0915-0925  Review of WCRP events, developments:
JSC-XXVII session, Pune, India  -J. Mitchell

0925-0935  CLIVAR SSG session and International CLIVAR Project Office  -G. Meehl
Input to the Regional Panels

0935-1030  Reports from WCRP Projects relevant to WGCM (10 minutes each)
- Stratospheric Processes and their Role in Climate (SPARC)  -N. McFarlane
- Climate and Cryosphere (CiC)  -D. Verseghy
- Global Energy and Water Cycle Experiment (GEWEX)  -C. Jakob
- Working Group on Surface Fluxes (WGSF)  -P. Braconnot
- WCRP Observation & Assimilation Panel (WOAP)  -G. Flato
- WCRP Modelling Panel (WMP)  - J. Mitchell

1030-1100  Coffee break

1100-1230  Reports from other WCRP modelling activities (10 minutes each)
- Working Group on Numerical Experimentation (WGNE)  -K. Taylor
- Working Group on Ocean Modelling (WGOMD)  -S. Griffies
- Working Group on Seasonal to Interannual Prediction (WGSIP)  -B. Kirtman
- Regional Modelling-update  -F. Giorgi

IPCC
- Fourth Assessment – update  -G. Meehl
- Workshops  -J. Mitchell/G. Meehl/K. Taylor
- Task Group on Climate Impact Assessment (TGCIA)  -J. Mitchell
- Task Group on New Emissions Scenarios (TGNES)  -N. Nakicenovics

Baseline emissions scenarios
Scientific issues in interpolating between scenarios, including Extremes, Maximum no scenarios. Modelling groups could expect/ be willing to run for IPCC AR5

1230-1345  Lunch break

1345-1530  News from relevant national and multinational projects (10 minutes each)
- Earth Simulator, Japan  -M. Kimoto
- Programme for Climate Model Diagnosis and Intercomparison (PCMDI), USA  -D. Bader
- Program for Integrated Earth System Modelling (PRISM), Europe  -J. Mitchell
- Australian Community Climate and Earth System Simulator (ACCESS)  -C. Jakob
- Canada Climate Change Model (CCCM)  -G. Flato
Coupled Modelling Groups, France - P. Braconnot
Coupled Modelling Groups, Japan - M. Kimoto
Hadley Centre, UK - J. Mitchell
Geophysical Fluid Dynamics Laboratory (GFDL), USA - T. Delworth
National Center for Atmospheric Research (NCAR), USA - G. Meehl

1530-1600 Coffee break

1600-1630 Identification of priorities for the rest of the meeting - J. Mitchell/G. Meehl
1630-1700 Data Management issues - R. Stouffer/K. Taylor
  - Steering Committee for CF metadata conventions

1700-1800 WGCM activities
  - Coupled Model Intercomparison Project (CMIP) - G. Meehl/C. Covey
  - CMIP/IPCC model analysis - G. Meehl
  - International Cloud Feedback Model Intercomparison Project (CFMIP)/Idealized experiments - S. Bony

1800 Listing of main issues and decisions of the day and Close of day’s session

**DAY 2 Tuesday, September 26**

0900-0930 WGCM activities (continued)
  - Forcing scenarios - R. Stouffer to lead
  - Initialization of models - R. Stouffer
  - Climate Change Detection, ET/CCD - D. Karoly

1030-1100 Coffee break

1100-1230 WGCM activities (continued)
  - Paleoclimate Modelling - P. Braconnot
  - Atmosphere–Ocean variability and predictability on decadal timescales - T. Delworth, M. Giorgetta
  - Carbon cycle modelling - C. Le Quéré

1230-1400 Lunch break

1400-1530 WGCM activities (continued)
  - ESSP/Global Carbon Project(GCP) - C. Le Quéré
  - Follow up actions from JSC-27 Recommendations
    - WGCM to lead Task Team on ACC
    - WGCM to lead Pan-WCRP effort on Decadal Predictability
    - WGCM and other activities to set up a Task Team to develop and deliver WCRP’s capacity to the UNFCCC

1530 - 1600 Coffee break

1600-1800 WGCM activities (continued)
  - Interaction with WMP, WGNE, WGSIP, WGOMD and WCRP projects
  - Workshop on Systematic Errors in Climate and NWP Models - P. Gleckler
    February 12-16, 2007
  - Review of decisions, future directions

**Closed session**
  - Membership issues
  - Next Session: venue, dates
Joint WGCM-AIMES session, Victoria, BC, Canada, 27 September 2006

Agenda

DAY 3 Wednesday, September 27

0845-0900 Welcome and outline of joint WGCM-AIMES session (J. Mitchell, D. Schimel)
0900-1230 Session: G. Meehl to lead
0900-1000 Overview/summary of Aspen Workshop
0900-1000 Response/discussion from non-Aspen participants
1000-1030 Discussion
1030-1100 Coffee break
1100-1200 Review of modelling group responses to survey regarding near-future modelling plans
1200-1230 Discussion
1230-1400 Lunch break
1400-1500 Session: D. Schimel to lead
1500-1530 Coffee break
1530-1700 Session J. Mitchell to lead
1700 Closure of the session
### Agenda item(s) | Actions/Recommendations | Responsibility
--- | --- | ---
CLIVAR | CLIVAR wanted to know from WGCM what processes do WGCM want to see better observed as inputs to CLIVAR panels to plan field projects? Particularly, the ocean observations. | Co-Chairs, WGCM

ClC | Interaction between WGCM and CliC to be enhanced to address uncertainties in sea level rise, in terms of Advanced Spaceborne Thermal Emission and Reflection radiometer (ASTER) images. Some sort of MIP (on century time scales) is needed. Other issues are ice sheet modelling, regional patterns of sea level change. One doesn’t understand why they appear as they do in models and understand them. | Co-Chairs, WGCM

GEWEX | There is need in WCRP to prioritize our activities. Need to identify major problem regimes and design model improvements. One way is to have metrics. Priorities to GEWEX: WGCM to provide cloud specifications providing our expectations; WGCM to interact with Chair, GMPP | Co-Chairs, WGCM Chair, GMPP

WCRP Modelling Panel (WMP) | Recommendations needed from WGCM to JSC on WMP issues | Co-Chairs, WGCM

Task Group on New Emission Scenarios, TGNES | WGCM proposed that modellers should be on TGNES; these modellers should be of IPCC type. WGCM to interact with R. Moss, co-chair, Task Group on Data and Scenario Support for Impact and Climate Assessment (TGCIA) | Co-Chairs, WGCM

WGSIIP | WGCM to have a session in Seasonal Prediction Conference, Barcelona, June 2007. | Co-Chairs, WGCM

IPCC | Letter from WCRP on scenarios to IPCC. | DWCRP

Earth System Modelling (ESM) | ESM experiments | G.A. Meehl

CMIP | G.A. Meehl) has decided to step down as chairman of CMIP and R. Stouffer (a CMIP Panel member since its inception) has agreed to become the new CMIP chairman. Additionally, C. Covey (another original CMIP Panel member) has agreed to become CMIP vice-chair. G.A. Meehl will stay on as a CMIP Panel member in addition to his duties as co-chair of WGCM. |
<table>
<thead>
<tr>
<th>CFMIP</th>
<th>CFMIP to be co-owned by GEWEX and GMPP</th>
<th>Chair GMPP, Chair GCSS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decadal</td>
<td>WGCM should interact with WGSIP. T. Delworth to be WGCM contact to coordinate with WGSIP in contact with WGSIP chair, B. Kirtman.</td>
<td>T. Delworth</td>
</tr>
<tr>
<td>Predictability</td>
<td>SPARC has great interest in decadal predictability and will raise it in the SPARC SSG meeting. The issue of chemistry coupled models for the next round of WCRP decadal simulations was discussed. SPARC was requested to provide stratospheric Ozone projections. It was recommended that M. Giorgetta should represent WGCM in SPARC SSG meetings. GEWEX should be in the context of drought. WGCM also recommended that PMIP should be in as they have the data. WGCM should also contact the CPC Merged Analysis of Precipitation (CMAP). WGCM expressed the need for Pan-WCRP group on Decadal prediction.</td>
<td>N. Macfarlane, M. Giorgetta, Chair, GMPP, P. Braconnot, G. A.Meehl, T. Delworth, B. Kirtman</td>
</tr>
<tr>
<td>C4MIP</td>
<td>WGCM was requested to help in 1. increased coordination on the water cycle 2. archiving strategy for C-cycle runs.</td>
<td>Co-Chairs, WGCM</td>
</tr>
<tr>
<td></td>
<td>WGCM was informed that PCMDI is dealing this issue with NCAR. WGCM suggested that C. Le Quéré should contact K. Taylor, PCMDI.</td>
<td>C. Le Quéré</td>
</tr>
</tbody>
</table>
| Data Management (DM) | 1. CF Governance Panel: to be appointed by WGCM  
WGCM to set it up and review it next year  
2. Should a set of benchmark experiments be established for climate models? WGCM agreed to this and asked for list to be proposed.  
3. Should data base be opened up further? WGCM expressed that this data base need not be thrown open to public; only for research purposes  
4. What DM issues /concerns are there related to preparation? WGCM expressed that there should be responsibility imposed on data users. | Co-Chairs, WGCM, K.A. Taylor |
SUMMARY REPORT
A STRATEGY FOR CLIMATE CHANGE STABILIZATION EXPERIMENTS WITH AOGCMs AND ESMs
Aspen Global Change Institute 2006 Session Earth System Models: The Next Generation
(Aspen, Colorado, July 30-August 5, 2006)

May 2007

19. Gerald Meehl, NCAR, Boulder, CO
20. Dave Lawrence, NCAR, Boulder, CO
21. Jean-Francois Lamarque, NCAR, Boulder, CO
22. Linda Mearns, NCAR, Boulder, CO
23. Peter Gent, NCAR, Boulder, CO
24. Sue Bookhout, AGCI, Aspen, CO
25. Michelle Masone, AGCI, Aspen, CO

Acknowledgments

We acknowledge the Aspen Global Change Institute that hosted the workshop in September, 2006, with support from NASA and agencies of the U.S. Global Change Research Program, led by director John Katzenberger, Sue Bookhout, and Michelle Masone who facilitated the very productive summer session where the first details of the research strategy outlined in this white paper were formulated.
**A Strategy for Climate Change Stabilization Experiments with AOGCMs and ESMs**

*Aspen Global Change Institute 2006 Session: Earth System Models: The Next Generation*

Report from Aspen Global Change Institute session, July 30-August 5, 2006 and joint WGCM/AIMES Steering Committee Meeting 27 September, 2006

Gerald A. Meehl and Kathy Hibbard
(and session participants—see list inside front cover)
July 23, 2007

**Executive summary**

We are now on the threshold of including Earth system model (ESM) components in “standard” global coupled climate models used for climate change projections. At present, these standard models (referred to generically as atmosphere-ocean general circulation models or AOGCMs) include components of atmosphere, ocean, land and sea ice. Some modeling centers have incorporated simple carbon cycle models into AOGCM’s (e.g., Cox et al. 2000, Friedlingstein et al. 2006), and additional candidate components include aerosols, chemistry, and dynamic vegetation (Figure 1), as discussed below.

Modeling groups are now making decisions on what form their next generation models will take to be used for climate change projections as well as a possible IPCC Fifth Assessment Report (AR5). The integrated assessment modeling community and others continue to develop new emission scenarios (e.g. mitigation/adaptation, also referred to as stabilization). The 25th IPCC Session (April 2006) recommended that the following four elements be addressed in the development of new scenarios: (1) Consistency between scenarios used for studying climate change, climate change impacts and adaptation and mitigation, (2) Comparability of scenarios by using comparable definitions and assumptions (the content of the definitions and assumptions should be entirely defined by the scientific community itself), (3) Transparency and openness of the development process; and (4) Substantive involvement of experts from developing countries and economies in transition in the scenario development process. The climate modeling community, however, does not have the expertise to evaluate and choose the appropriate subset of scenarios to run. Therefore, it has become evident that a new set of experiments be designed as part of a coordinated research strategy to address the climate changes associated with possible stabilization of atmospheric CO₂ concentrations. The experimental design proposed in this report reflects a coordinated effort between the climate modeling and integrated assessment communities to address the first three recommendations, with an extra effort needed towards the fourth. The new scenarios will come to bear on coordinated climate change projection experiments for possible assessment in the IPCC AR5 with the new emerging Earth system models.

There has therefore been a confluence of activities in climate model and scenario development that must be communicated and coordinated across various groups and scientific communities in a timely fashion to begin a next assessment process. To this end, a session of the Aspen Global Change Institute was convened from July 30-August 5, 2006, to address four major objectives:

1. Identify new components that are currently under implementation or will be ready in the next six months for inclusion as first generation Earth System Models in Atmosphere-Ocean General Circulation Models (AOGCMs).
2. Establish communication through WCRP, IGBP, IPCC, the climate impacts community, and integrated assessment (IA) modeling teams to coordinate activities in preparation for climate change simulations that will be performed with this next generation of climate system models for a possible IPCC AR5.
3. Propose an experimental design for 21st century climate change experiments with these models (near term and longer term time frames).
4. Specify the requirements for these new models in terms of time series of constituents from new stabilization scenarios (particularly with regard to impacts, mitigation, and adaptation).
Updates for emerging Earth system models regarding current status of new components, along with scientific issues involved with coupling these components were discussed. The status of carbon cycle and dynamic vegetation to be incorporated in AOGCMs include:

- Empirical evidence indicates that the carbon cycle responds to climate change, and first generation coupled carbon cycle models indicate the possibility of a large positive carbon cycle feedback to global change (Cox et al. 2000, Fung et al., 2005, Friedlingstein et al. 2006, Meehl et al. 2007a). This makes the challenge of achieving any particular stabilization target more difficult to achieve. Therefore, the community is moving towards including aspects of the terrestrial and ocean carbon cycle and dynamic vegetation in the next generation Earth system models.

- Some models already include a closed carbon cycle, but none have yet consistently included the impacts of land use change, land management, and wild land fires. These dynamics are under development in some groups and will be a priority.

- We also expect some models to include a representation of ocean biology.

- Although all models won’t include other potentially important processes such as micronutrient limitations on ocean ecosystems, ocean bottom chemistry, nutrient limitations on terrestrial ecosystems (e.g., nitrogen), impact of anthropogenic managements on fires and increases in tropospheric ozone, it is anticipated that some models may be implementing some or all of these.

- Modeling groups are also implementing various strategies for biogeography and successional processes.

Summary points for aerosols and chemistry to be incorporated in AOGCMs include:

- Aerosols and chemistry need to be considered in Earth system models for a number of reasons, including aerosol composition, effect of pollution on the biosphere and air quality. Indeed, a new consideration is the ability of the ESM to provide insight into air quality trends, for use by impacts and scenario communities.

- Most models will have a representation of the indirect effect of aerosols. However, mixed phase and ice phase cloud-aerosol interactions are likely to be handled rather crudely and are a subject of ongoing research.

- The representation of aerosols and chemistry is likely to be more comprehensive for near-term (2005-2030) than for long term (2100 and beyond) experiments partly due to computational resource limitations and computing demands. In addition, the climate effects of aerosols and chemistry are expected to be particularly important over the near-term time frame.

Another important new component under development relates to prognostic interactive ice sheet models. However, these components, though likely to be included in some next generation models, will not be part of the coordinated experiments discussed here.

Taking into account the state-of-the-art of these new components, session participants (who represented relevant communities involved with WCRP, IGBP, the former Task Group on New Emissions Scenarios (TGNES), and IPCC Working Groups I, II and III), proposed an experimental design for coordinated community climate change experiments that would be relevant to a next IPCC assessment. Subsequent to the AGCI session, a joint meeting between WGCM and AIMES in September, 2006 further discussed the proposed experimental design for the community climate change experiments that fell into two timescales involving different scientific problems, policy considerations, scenario issues, and model configurations. This report summarizes the experimental design proposed at the Aspen Global Change Institute session and further developed during the joint meeting.

**Proposed AR5 Experimental Design for Coordinated Climate Change Projections**

1. **Near term (2005-2030)**
The primary goal of projections for the next 25 years is to provide better guidance as to the likelihood of changes in extremes on the regional scale. This depends on scientific questions involving understanding the physical processes that produce such extremes related to the hydrological cycle, and relevant atmospheric and oceanic processes operative on that timescale. To produce such regional scale predictions could require finer resolution models (at least ½ to 1 degree latitude/longitude in the atmosphere, but other resolutions are possible, as well as increased vertical resolution and domain) with the inclusion of simple chemistry, aerosols, and dynamic vegetation, but an interactive carbon cycle is not required on this timescale. Both improved process representation and higher resolution are important and compromises will be required to make the simulations computationally feasible.

To determine the significance of regional changes, especially those of extremes, will require numerous simulations in an ensemble approach. Given that scenarios of long-lived greenhouse gases do not differ substantially prior to 2030, a single, mid-range scenario is anticipated to be used in model predictions for this near-term timescale. For this time frame, the relatively small magnitude of climate change will make signal to noise discrimination even more difficult. The number of ensemble simulations to be performed is somewhat uncertain, but a minimum of 10 ensemble members for each case should be performed and discriminating changes in hydrologic processes that contribute to precipitation extremes may require even more.

Two options for additional experiments were identified: (1) Several scenarios for pollutants (aerosols and short-lived gases) to study their effects on weather could be provided for low, medium and high emission projections as perturbations around the standard scenario, and (2) Testing geo-engineering hypotheses (e.g., injecting sulfur into either the stratosphere or troposphere) with model experiments to mitigate climate change. Interactions and feedbacks to the climate system would nevertheless need to be explored with ESMs to try and ascertain unintended consequences on other Earth System model components such as ecosystems and atmospheric chemistry.

These near-term simulations could use a coupled initialized state close to the present-day state of the climate system. This would require accurate representation of, for example, ocean salinity data and soil moisture which are currently problematic due to sparse observations, and improved initialization datasets of sea ice may be required. Simulations should start during the latter half of the 20th century in order to incorporate past climate forcings to account for: (1) radiative imbalances that produce short-term committed climate change, (2) facilitate model verification and evaluation; and (3) the logistics involved with the coupled assimilation/initialization process.

2 Long term (2005-2100 and beyond)

The goal for longer term projections is to quantify the various feedbacks in the climate system involving Earth system components related to climate outcomes for different scenarios that could be affected by various socio-economic and policy considerations (e.g., stabilization). Therefore, coupled initialization would not be recommended for long term runs (e.g., 1850-2100/2300) as the model initial conditions for a time in the late 1800s are from pre-industrial control runs. A lower resolution AOGCM (roughly 2°) could be used with a more conventional pre-industrial spin-up, followed by a 20th century experiment with natural and anthropogenic forcings (at least 10 member ensembles would be required for detection/attribution studies), leading to an A1B-type mid-range 21st century experiment as a single member. This set-up would correspond to what was done for the IPCC AR4 and would provide a reference to earlier experiments, as well as supply a multi-model ensemble of a mid-range scenario for analysis. Two benchmark stabilization scenario experiments would then be performed:

1. high forcing, perhaps A2-type stabilization scenario
2. low forcing, perhaps B1-type stabilization scenario

At least one ensemble member would be run for each, with carbon cycle and biogeography active, and prescribed, transient chemistry and aerosols. Initially the experiments would be run to 2100, then concentrations stabilized after 2100 following the prescribed concentration scenario, and the models run out to 2300. Two experiments from 2005 to 2100 would be run for each scenario:

Experiment 1: Long term benchmark stabilization. Both AOGCM and AOGCMs coupled to the carbon cycle (ESMs) run with a time series scenario of prescribed CO₂ concentrations. In this run, the climate system is allowed to respond to prescribed CO₂ concentrations. Coupled carbon cycle-climate ESMs produce time series of
CO₂ fluxes from the land-atmosphere and ocean-atmosphere that do not enter the atmosphere or impact the climate system response. The internally calculated land/ocean CO₂ fluxes plus the prescribed increase in atmospheric CO₂ produce an implied CO₂ emission rate (F₁(t)) and are provided to WG3 and IA modeling groups to derive mitigation policies to achieve those allowed emissions. Non-ESM groups (standard AOGCMs) without a carbon cycle component can also run this experiment to derive climate system response to changing CO₂ concentrations as occurred in the AR4.

**Experiment 2: Carbon cycle response to increasing concentrations.** This experiment evaluates the carbon cycle response to increasing CO₂ concentrations without climate change feedbacks. It is similar to Experiment 1, with the exception that the atmospheric CO₂ concentrations are held constant at pre-industrial levels for radiative calculations in the atmosphere, but the other ESM components respond to the increasing CO₂ concentrations from Experiment 1 (Figure 2). The derived emissions from Experiment 2 represent the carbon cycle feedback reacting only to the prescribed increasing atmospheric CO₂ concentrations. Comparing the derived emissions from Experiments 1 and 2 provides an indicator of the magnitude of the carbon cycle/climate feedback in terms of those different emissions.

**Experiment 3: Emissions driven carbon cycle/climate.** Though not finally determined, a couple of options for a third experiment are proposed that involve an emissions-driven carbon cycle/climate simulation driven by emissions rather than concentrations to quantify the climate response with an active carbon cycle. One option would be for this experiment, to be compared to the 1% per year CO₂ increase experiments which are now standard for AOGCMs, is to quantify the transient climate response (TCR), or the globally averaged surface air temperature increase at the time of CO₂ doubling. This experiment would then use an emission time series comparable to 1% per year CO₂ concentration increase, and then run with fully interactive carbon cycle feedbacks that can change the atmospheric CO₂ concentrations. The difference between this experiment and the 1% per year CO₂ increase experiment would give the magnitude of the carbon cycle feedback in terms of the climate response (e.g. temperature). Such an experiment would provide a direct connection to the C₄MIP experiments (e.g., Friedlingstein et al. 2006) as well as to the standard idealized 1% per year CO₂ increase experiments run with AOGCMs. Another possibility being discussed for this experiment would be to take the emissions used to derive the benchmark concentration scenarios in experiment 1, run the fully coupled ESMs with those emissions, and compare the climate response to experiment 1 to assess the magnitude and nature of the climate feedbacks involved with the carbon cycle.

This experimental design has a number of desirable features as well as requirements:

- Different timescales of climate change projections require different approaches in terms of model configurations and scientific and policy problems of interest.
- Relatively few future climate projection simulations would be required of the ESMs using two new benchmark stabilization scenarios (for high and low forcing). For the AR4 there were three future climate projection simulations. For the proposed new coordinated experiments, there would be a minimum of three simulations for groups with ESMs, and two for groups with AOGCMs. If it is desired to run an intermediate stabilization scenario as well, that would be one more additional experiment.
- Non-ESM results can be directly compared with the ESM results for the physical climate system (modeling groups without new Earth system components (e.g., no carbon cycle) can still participate by running either the near-term projection, the longer term projection (just Experiment 1), or both.
- Using benchmark stabilization concentration scenarios allows the WG3 community to provide these scenarios to the WG1 community in a timely manner without the WG1 community having to evaluate and choose individual scenarios, this being outside their area of expertise. The development of a complete new set of scenarios would take several years and WG3 have assessed revised SRES and some new scenarios (from the literature) that are available immediately. Based on these revised SRES and corresponding stabilization scenarios, WGI supplies emission time series back to WG3 scientists, who derive socio-economic constraints to achieve those emissions stabilization pathways. This is the reverse of what has typically been done up to now (i.e. with socio-economics as the starting point, generating emissions,
concentrations, climate response, impacts analysis). Impacts are analyzed from the climate response experiments as before. WG3 will therefore evaluate socio-economic assumptions to achieve stabilization.

- The process involved with this experimental design establishes pathways for necessary interactions between WG1 and WG3 communities. Community groups that can coordinate activities across their respective communities (e.g. the WCRP Working Group on Coupled Models (WGCM) for the AOGCMs, the IGBP Analysis, Integration and Modeling of the Earth System (AIMES) for biogeochemistry and biogeography) need to be formed for WG2 and WG3 to allow better overall coordination of these types of activities.

**Overall Recommendations:**

- An integrated effort is needed to produce past/current/future emissions of aerosols and ozone precursors that would ensure the use of consistent and documented data relevant to climate/carbon cycle/aerosol/chemistry communities.

- To assess regional climate change effects will require gridded emission data for aerosols and short-lived trace gases. A concerted effort will be necessary to produce these datasets.

- In order to use more up to date model projections for impacts results reported in IPCC WG2 assessment, model simulations need to be made available to impacts modelers several years before the production of the WG2 report. This could be done by either staggering the WG1 and WG2 reports or by producing new climate change simulations as soon as possible (about 2009-2010).

- There is a need for a PCMDI-equivalent for WG2 and WG3 communities where relevant climate model output can be collected, archived, and tailored for use by scientists in these communities. This could include an expanded role for the IPCC Data Distribution Center. A WGCM-type community organization mechanism is also needed for the WG2 and WG3 communities.

- WG2 and WG3 scientists need to have input to the selection of fields to be archived for analysis in the new integrations for the AR5, in particular a list of fields related to the carbon cycle.
1. Introduction

In IPCC Fourth Assessment Report (AR4), a common or core set of integrations was performed by sixteen climate modeling groups (Meehl et al. 2007b). These integrations allowed the assessment of model response uncertainty to changes in the radiative forcing. The simulation of past climate changes led to identification of model errors in the simulation of present day climate and improved estimates of the human impact on climate. The future climate projections sampled the range of uncertainty associated with the various scenarios used to drive the climate models, and the uncertainty associated with the model response to the imposed forcing changes.

In the AR4 common set of integrations, three future scenarios were used by most modeling groups: the draft or marker SRES A2, A1B and B1 scenarios. Twenty-three different climate models were used to make the future climate projections. The range of model responses for a given scenario represents a measure of the model response uncertainty.

An Earth System Model (ESM) simulates processes in the climate system involving the major components of atmosphere, ocean, land and sea ice, and also includes forcings and feedbacks involving the biosphere, and composition and chemistry of the atmosphere and ocean of potential importance to the physical climate (e.g. carbon cycle, aerosols, chemistry, and dynamic vegetation) (Figure 1). Such ESMs can be used as tools to study climate impacts which are dependent on climate change, to inform climate mitigation strategies such as avoiding dangerous climate change (e.g. Amazon dieback) or verifying plausibility and providing consistency with scenarios (e.g. air quality control policy, food production, biofuels, and costs of adaptation). The ultimate ESM would include every known process in the physical and biogeochemical earth system. Clearly at this stage we are not yet at that point, so we will be discussing ESM-type configurations with simplified biogeochemical components. For simplicity, we will refer to these models as “ESMs”.

The current status of modeling the Earth system is characterized by sophisticated global coupled climate models of the physical climate system including components of atmosphere, ocean, land surface and sea ice (Fig. 1, upper left). These are often referred to simply as atmosphere-ocean general circulation models or AOGCMs. The climate modelling community is now considering expanding these already complex models to encompass chemical and biological aspects of the Earth System. In particular, AOGCMs are now beginning to implement detailed sub-models, or components, of atmospheric chemistry, the carbon cycle, aerosols, and dynamic vegetation (Fig. 1, lower left).

Ice sheet models are also being considered for inclusions in ESMs by some groups, though their implementation has lagged somewhat the other components. Thus, though some form of dynamic ice sheet models will be included in some versions of the next generation ESMs, they remain as elements of purpose-driven experiments to test the responses of ice sheet dynamics and will not be encompassed in the coordinated experiments proposed here.

Currently, output from AOGCMs can either used to produce information on climate change impacts on line if the impact is dependent on the weather that is being simulated (e.g. heat waves), or if the impact feeds back on climate (e.g. soil moisture changes). If the impact is just dependent on the climate being simulated, the impacts can be determined separately or offline using various types of impact models or methodologies (Fig. 1, right). These can include models directly using AOGCM or ESM output (e.g. crop models) or, if higher resolution information is required, statistical downscaling or embedded regional models driven by output from the AOGM can be employed.

Earth System Models of Intermediate Complexity (EMICs) offer a complementary approach for long-term simulations. EMICs span a wide range of a hierarchy of more simplified models, but usually include coupled processes in a reduced domain (e.g. two dimensional), and can capture some of the essential feedbacks while using far less computer resources than a typical AOGCM or ESM. EMICs can therefore be used to run many more scenarios for much longer time periods than typical AOGCMs or ESMs, and can provide first order information on global temperature and sea level response (but not information on changes of variability or extremes). More holistic, exploratory models are being developed for the investigation of the interaction of human societies with the other components of the Earth System.
We are entering a crucial period of climate model development where several communities now have functioning components, beyond the traditional global coupled model components of atmosphere, ocean, land surface and sea ice, that could be included in global coupled ESMs. These new components include carbon cycle, dynamic vegetation, aerosols and atmospheric chemistry. Developments across these disparate communities have been rapid, and it is urgent that these communities communicate closely regarding the form the next generation ESMs will take, with particular application for a possible IPCC Fifth Assessment Report (AR5).

Scientists working in these fields as well as members of a number of international panels representing these various communities met in July 2006 at an Aspen Global Change Institute (AGCI) session. Participants represented the Working Group on Coupled Models (WGCM) and Stratospheric Processes and their Role in Climate (SPARC) from the World Climate Research Program (WCRP), and Analysis, Integration and Modeling of the Earth System (AIMES) and the International Global Atmospheric Chemistry program (IGAC) from the International Geosphere-Biosphere Program (IGBP). In addition, representatives from the emissions scenario (IPCC WG3 and the now-disbanded Task Group on Next Emission Scenarios (TGNES)), climate change impacts (IPCC WG2, and Task Group on Data and Scenario Support for Impact and Climate Analysis (TGICA)), and the integrated assessment communities were present. The purpose of this workshop was to define a roadmap to accelerate progress in ESMs at the international level. Several scientific issues were considered at this workshop, for example, aerosol/cloud/climate coupling, and vegetation/ocean/biogeochemistry/climate feedbacks. The central question for the workshop was: what should be the strategy to improve our ability to model with more certainty these processes, what form will these processes take in the next generation of earth system-type models, and what would be an experimental design to address future climate change in these models with new scenarios?

The outcomes and recommendations from the joint AGCI session provided fuel for discussion at a joint WGCM/AIMES meeting in September 2006 as well as the Earth System Science Partnership (ESSP) Open Science Conference in Beijing in November 2006. The objective of the workshop was to establish a coherent approach through WCRP and IGBP (jointly), and to "distribute" the responsibilities and tasks between the different IGBP and WCRP Projects in preparation for climate change simulations that would be performed by this next generation of models for the IPCC AR5.  The workshop had four general objectives:

1. Identify new components that are currently under implementation or will be ready in the next six months for inclusion in AOGCMs.
2. Establish communication through WCRP, IGBP, IPCC, the climate impacts community, and integrated assessment (IA) modeling teams to coordinate activities in preparation for climate change simulations that will be performed with this next generation of climate system models for the IPCC AR5.

3. Propose an experimental design for 21st century climate change experiments with these models (near term and longer term time frames).

4. Specify the requirements for these new models in terms of time series of constituents from new stabilization scenarios (particularly with regard to impacts, mitigation, and adaptation).

This report outlines a strategy for the new AOGCM/ESM modeling components in terms of aerosols/atmospheric chemistry and carbon cycle/dynamic vegetation components that are under development and implementation in ESMs that involves a proposed experimental design that integrates impacts and scenarios (represented in IPCC WG2 and WG3, respectively) and physical climate science (WG1). We summarize with a suite of recommendations for the joint WGCM, AIMES and IPCC communities. An abbreviated version of this white paper has already appeared (Hibbard et al., 2007).

2. New ESM components for inclusion in AOGCMs

Aerosols and Chemistry

Aerosols are important to the climate system for many reasons. They have a direct effect on heating and photolysis rates in the atmosphere by scattering and absorbing radiation. They influence the climate system indirectly by modulating cloud drop size, cloud lifetime, and precipitation, and there are other processes such as the “semi-direct” effect involving subtle modulations of the dynamical and physical processes of the atmosphere. Aerosols also act on other components of the climate system by reducing energy reaching the surface, and by transporting nutrients from one place to another. There are well documented changes in aerosol distributions due to mankind during the last few hundred years and some more changes are anticipated in the future.

There are also many photochemical processes taking place in the atmosphere which are affected by mankind. These processes influence aerosol formation and properties, and affect the climate system directly. The changes in the chemistry of the troposphere are of concern for a variety of reasons. Air quality near the Earth’s surface affects humans and ecosystems. Many aerosols are formed or influenced by chemistry (the oxidation of precursor gases to sulfate, nitrate, and secondary organic aerosols is an obvious example).

Simulating the chemistry of the atmosphere, the interactions with aerosols, and the interactions of these components with other components of the climate system are enormously complex, and computationally very costly. These components cannot be represented comprehensively in today’s AOGCMs. Simplifications must be made, and many aspects of their interactions must be ignored to be able to include them in the emerging ESM-type models. We recognize that complexity could be different for short- (up to 2030) and long-term simulations (to 2100 and beyond). In this section, we discuss some of the properties of aerosols and chemistry of the climate system which we believe are needed for the next generation of ESMs, and identify the simplifications that are appropriate in their treatment.

1. The radiative forcing by tropospheric ozone is believed to be globally small, however, it is not negligible regionally. Some representation for this effect should be employed. One way to implement this is through “time slice” photochemistry, where a reasonably comprehensive photochemical model is occasionally employed offline (e.g. a one year simulation performed once every 10 years). There may be other alternative efficient methods of producing photochemical information in the model.

2. One simplification to represent tropospheric O₃ that is frequently used in today’s ESMs is the use of prescribed oxidant distributions (OH and O₃ for example in the oxidation of SO₂ to sulfates). Alternatively, extreme simplifications to the photochemistry can be employed (the chemistry of peroxides in the oxidation of SO₂ to SO₄ in clouds). While limited treatment of most aerosols can be achieved though the use of these off-line oxidants, it is clear that an improved treatment may be required for the formation of secondary organic aerosols.
3. A number of climate feedbacks should be explored more thoroughly for the climate change problem including, but not limited to:

- Temperature => isoprene emission => ozone => temperature
- Temperature => monoterpenes emission => SOA => temperature
- Climate change => DMS => sulfates => temperature
- Climate change => lightning, fires, wetlands => O₃, CH₄, aerosols
- Climate change => vegetation cover => dust emissions => climate
- Preliminary studies indicate however that these feedbacks are likely to be not very strong; but many are positive and may add up to something larger.

4. Aerosols and some reactive chemical species (mostly ozone, carbon monoxide and nitrogen oxides) are important for impact assessments of air quality as they have a large impact on human health and crop (and more generally vegetation) yield. The occurrence of ozone episodes and nitrogen deposition can strongly impact the carbon cycle. These species should be considered in this context for the present proposed modeling strategy.

5. Interactive modeling of stratospheric ozone would alleviate the current difficulties of merging independent characterizations of ozone from tropospheric and stratospheric chemistry at the tropopause.

6. It is estimated that air quality controls may result in additional heating over the next two or three decades (because of the removal of cooling aerosols). These controls may also have an impact on precipitation over the same time scales. Feedbacks involving the vegetation (mostly ozone poisoning and nitrogen deposition) operate over multi-decadal to century timescales. Overall, the consideration of aerosol and chemistry in the next set of coordinated climate change simulations will require more interaction with the integrated assessment modeling community. For this effort to be successful, consistency with assumptions made in emission scenarios (including land use) will also be required.

A. Representing aerosols and chemistry in the near- and longer-term

In many climate modeling centers, the capability for simulating aerosols exists but the computational cost of additional tracers and processes is an issue that limits their applicability to climate assessment exercises. This is becoming even more of an issue when more complex aerosol formulations are being considered. Furthermore, it is important to keep in mind that the knowledge of driving inputs (e.g. characterizing the number of primary aerosol particles emitted, individual VOC species emissions, and the vertical profiles of emissions) might be insufficient to run the most complex versions over the historical or future periods. It is unclear at this point if the full complexity is required for IPCC-type simulations. Therefore simplified versions are currently under investigation. For instance (1) bulk versus modal approach for aerosols, (2) simplified versus comprehensive gas-phase chemistry, and (3) asynchronous versus full reactive chemistry coupling.

An evaluation of these different alternatives is well underway through the participation of the various modeling groups who are involved in intercomparison exercises such as AEROCOM, CCMval, ACCENT, and the new Atmospheric Chemistry and Climate (AC&C) initiative under the auspices of SPARC and IGAC. However, it is recognized that there is a need for more coordinated intercomparison studies and common diagnostics. This should lead to more insight into what should be included in the next generation of ESMs.

The following table summarizes the status of the developments planned within the various groups represented at the Aspen workshop with respect to the aerosol and chemistry packages that will most likely be included in the core version of their climate models to be used for the next set of coordinated climate change experiments. This is only a subset of the total number of modeling groups making plans for such experiments, but this list is representative of the activities at the larger number of modeling groups.
**Model Center/Aerosols**  
**Chemistry**

| Within about 1 year (ready to run for next IPCC) | GISS: Sulfate / BC / OC / dust / sea-salt driven from DGVM / sea-salt / SOA climatology  
Hadley: bulk, sulfate /BC / OC / dust driven from DGVM / sea-salt / SOA climatology  
NCAR: Both bulk and modal approaches are available and being considered  
MPI: A seven-category modal approach predicting total number and species mass in each category (M7)  
Limited ability to represent aerosol indirect effect processes, especially in mixed phase, ice and convective clouds. | Cost is under evaluation for all groups.  
At least snapshots / asynchronous coupling will be done with full chemistry (tropospheric and stratospheric) with a coupling every 5/10/20 years? |
|---|---|---|
| Beyond AR5 | Full aerosol scheme  
Comprehensive mixed and ice phase cloud microphysics | Full chemistry |

In summary, most models will have a representation of the indirect effect of aerosols and the considered aerosol schemes will be much more comprehensive than in AR4, including more species, and treating their temporal change from past to the future. The representation of chemistry has to be more comprehensive for the near-term (2005-2030) than for the long-term (2100 and beyond) experiments. Beyond the next set of coordinated experiments, it is expected that all modeling centers will have access to enough computer power to be able to have a full representation of aerosols (for both mass and number) and gas-phase chemistry.

**B. Aerosol and chemistry considerations for an experimental design**

For the simulation of aerosols and chemistry, a critical item is the knowledge of historical and future emissions, which have to be consistent. In particular, because of the developments in the simulation of aerosols, it is necessary to build and assess historical emissions beyond sulfur. These include black carbon and primary organic carbon (with some information on size if possible) and ozone precursors. The more comprehensive chemistry schemes will also require the development of a detailed speciation of volatile organic compounds (VOC) emissions. For both gaseous species and aerosols, the knowledge of emissions for different sectors is needed as emission factors and speciation depend on the emission type. In all cases, the knowledge of injection heights (smoke stacks, airplanes, biomass burning, etc.) is an important additional piece of information.

Recent studies of the carbon cycle indicate that over the past 100+ years, as a result of fire suppression policies, large areas of the western US and Canada (and possibly other parts of the world) have experienced a large decrease in fires and open burning, in contradiction with the usual assumption of an increasing number of fires over the industrial period made in previous studies. The negative trend in fire emissions at mid-latitudes could have very significant impact on the present estimate of the radiative forcing of ozone and biomass burning over the pre-industrial to present-day period. In addition, the intensity of contemporary wildland fires, because of fire suppression practices, are not representative of historic low-to-moderate intensity, but rather, are becoming more catastrophic in nature for many forested systems. These higher intensity fires have different characteristic injection and emissions profiles than either pre-industrial or experimental and prescribed burns. In addition, the knowledge of historical and future land use (incl. ecosystem knowledge) is necessary for the representation of past dust and biogenic emissions.

Because of the existence of a variety of historical emissions, it is unclear what the appropriate level of guidance could or should be for defining whether a single set of emissions should be used and, if so, which one. In order to minimize the amount of simulations of interest to a variety of communities (IPCC, CLRTAP), a strong effort will be required to ensure consistency in the used past/present/future emissions.
There is a strong and urgent need for an increased dialogue and collaboration between the observation, measurement, modeling and scenarios communities that utilise past and current emissions relevant to gas-phase chemistry, aerosols and carbon cycle (e.g., GEIA and IGAC). An integrated assessment or a synthesis document discussing these emissions and providing expert evaluations would be extremely useful. Such a process should be coordinated at the highest level (IPCC, IGBP, WCRP, IHDP, CLRTAP), which would ensure the existence of a consistent set of input data usable by all the communities interested in climate change science and impacts over the historical and future periods.

C. Computer cost

Very rough estimates of the additional cost (with the atmospheric model using the same model resolution serving as a reference) of a fairly simple aerosol scheme range from 30% (Hadley Center) to 100% (NCAR). For tropospheric chemistry the overhead ranges from 50% (for simple chemistry version of the GISS model) up to a factor of 3 (NCAR) or 4 (Hadley) increase compared to the atmosphere model. It is clear that computer cost depends on how the atmospheric model is optimized and on the type of platform. In the case of NCAR, it has been estimated that, for transport only and ignoring other costs, there is an additional cost of 2-3% per added tracer.

D. Recommendations for implementing aerosols and chemistry components

- Aerosols and chemistry need to be considered in ESMs for a number of reasons. A new consideration for a coordinated experimental design is the ability of the ESM to study air quality trends, and to be used by the impact (WG2) and the scenarios (WG3) communities.
- For this next generation of models, most will have a representation of the indirect effect of aerosols using more comprehensive schemes than in AR4, and will treat their temporal change from past to the future.
- The representation of aerosols and chemistry is likely to be more comprehensive for the near-term (2005-2030) than for the long-term (2100 and beyond) experiments partly due to computational limitations.
- The expectation is that effects from aerosols and chemistry would be particularly important over this near-term time frame.
- Mixed phase and ice phase cloud-aerosol interactions are likely to be handled rather crudely in these new simulations. This is a subject of on-going research.
- An integrated effort to produce past/current/future emissions of aerosols and ozone precursors would ensure the use of consistent and documented data relevant to climate/carbon cycle/aerosols/chemistry communities.

Dynamic Vegetation and the Carbon Cycle

A. Model Strategies

“Core” components of the carbon cycle in new ESMs

The majority of major global models are expected to include several additional components into their carbon cycle modeling strategy. Taken together, these components “close” the global carbon cycle (i.e. allow calculation of the net land-atmosphere and ocean-atmosphere exchanges of CO₂ online within the ESM):

- Ocean biogeochemistry including simple ocean ecosystem (e.g. Nutrient–Phytoplankton–Zooplankton–Detritus (NPZD)) models.
- Terrestrial carbon cycle model (typically without nitrogen limitations) that simulates the water, energy, and carbon fluxes at the land surface.
- Vegetation dynamics – re-growth following disturbance including age class succession with limited Plant Functional Types (PFTs) (e.g. 5-15 PFTs) and in some cases dynamic biogeography (i.e. the ability to change the geographical distribution of PFTs).
- Anthropogenic land-use change (transient) with corresponding translation into net carbon fluxes including wood harvest.
- Land management – agricultural activity on cropland (e.g. irrigation, tilling), pasture and forestry.
- Fire - wildfire including affects on vegetation and soil carbon stocks.

It is important to stress that the response (and sensitivity) of the terrestrial carbon cycle depends heavily on the simulated precipitation and temperature of the climate model. A short set of climate metrics that need to be met in
order for a meaningful simulation of the carbon cycle to be possible should (and in some cases have already) be identified and delivered to developers of the physical model as early in the model development cycle as possible. The Köppen and/or Holdridge classifications may be useful diagnostic tools to help identify inconsistencies between the simulated temperature and precipitation regimes and the expected vegetation class. In the case where a solution to a temperature or precipitation bias that is detrimental to the vegetation distribution simulation cannot be found, it is preferable to avoid tuning the land or dynamic vegetation model to get the correct vegetation types (e.g. rainforest in the Amazon) and consider the resulting problems during analyses.

While many groups have already implemented, or are developing the above model components, there are technical and philosophical challenges when it comes to integrating the components. Coupling of the components should also occur relatively early in the development cycle to identify and counter unforeseen problems (e.g. programming errors, model instabilities).

Not all modeling groups will incorporate all of the DGVM and carbon cycle components in time for the planned coordinated climate change experiments. We may therefore wish to provide prescribed fields (e.g. of the CO₂ fluxes from land-use change), that will allow these models to participate in an intercomparison. Careful design of the model experiments are critical in this respect (see text on “Proposed Experimental Design”).

“Vanguard” components of the carbon cycle in ESMs by the time of IPCC AR5
The following “vanguard” elements are not likely to be incorporated into the majority of carbon cycle models but may be present in some models, and will therefore be used in “research-type” model experiments:

- Nitrogen cycling and nitrogen limitations on the terrestrial carbon cycle.
- Anthropogenic impacts on fire (including ignitions, suppression).
- More sophisticated ocean ecosystem models, with resolution of more phyto- and zoo- plankton functional groups.
- River biogeochemistry (especially dissolved organic carbon (DOC) fluxes from land-to-ocean).
- Micronutrient limits (e.g., Fe) on ocean biogeochemistry.
- Ocean bottom carbon chemistry, calcite formation (only important on 300-1000 yr timeframe, e.g. for stabilization scenarios)
- Interactive biogenic fluxes of methane, VOCs etc. (for coupling to atmospheric chemistry).
- Advanced vegetation dynamics with improved succession based-on more PFTs and possibly explicit dispersal mechanisms (the latter is only applicable in high-resolution ESMs).
- Multiple agriculture (crop x management) PFTs and associated local/regional land use practices
- Transient urban fractional cover.
- Improved spatial resolution of the land-surface based on either a higher resolution regular-grid and/or an irregular land-grid defined by river-catchments.
- Impact of tropospheric ozone on vegetation.
- Improved treatment of organic soils including carbon dynamics and links to thermal and hydraulic impacts of peatlands.

Coupling frequency
The land-atmosphere carbon fluxes need to be determined at every land-model timestep (typically 30 minutes) to ensure consistency with energy and water fluxes. Ocean-atmosphere fluxes will typically be calculated on the timestep of the ocean model and increment atmospheric CO₂ (in runs with prescribed emissions) on every ocean-atmosphere coupling period (typically 1 hour to 1 day). The terrestrial and ocean carbon cycle models will therefore be coupled synchronously, although a hierarchy of timescales is often used within the DGVM component (daily to weekly for phenology, monthly to yearly for dynamic biogeography).

Timescale of feedback
Although global carbon cycle feedbacks may not be readily apparent for 30 or so years, the biophysical response (e.g., albedo) to disturbances (fire, drought, timber harvest, etc) is detectable on much shorter timescales, e.g. annual, timescales.
B. Computer resources
The cost of adding the terrestrial carbon cycle may be around 20% of the atmosphere-land model (3-5% (GFDL); and as high as 30% (NCAR’s CCSM)), with most of this associated with the calculation of CO₂ fluxes on each timestep of the land model. By contrast, vegetation dynamics will be computationally cheap because it only needs to be updated fairly infrequently (monthly to yearly). Storage requirements for the land model increase significantly due to large increase in number of prognostic variables, but this increase is likely to be fairly insignificant in the context of the ESM as a whole.

Ocean biogeochemistry is likely to require a 2- to 5-fold increase to the computational cost of the ocean model due to a large increase in the number of tracers. Storage requirements will also increase considerably.

It is important to note that to bring the carbon cycle into equilibrium, computational requirements for a coupled carbon cycle model development and spin-up will significantly increase over those for a standard AOGCM.

C. Scenarios requirements and new requirements from the atmosphere model
- Global mean CO₂ concentrations for 1850-2100 (for runs with prescribed CO₂ but diagnosed anthropogenic emissions, see “Proposed Experimental Design”).
- Global anthropogenic CO₂ emissions from fossil fuel burning plus cement production for 1850-2100 (for runs with interactive CO₂).
- Global net CO₂ emissions from land-use change for 1850-2100 (for runs with interactive CO₂ in models that do not calculate land-use fluxes internally).
- Gridded land-use and land management information, including consistent disturbance history and future disturbance. It is critically important that the history and scenarios of land-use are consistent (i.e. without a discontinuity in going from past to future!).
- Gridded fire history reconstruction including area burned (disturbance) and emissions to the atmosphere from fires.
- National-level CO₂ emissions for the carbon cycle validation period (say 1960-2000). These emissions will be used in the coupled climate-carbon cycle models to assess their ability to reproduce seasonal changes and latitudinal gradients of atmospheric CO₂ concentration.
- Gridded nitrogen deposition fields for 1850-2100.
- Gridded near-surface ozone concentration fields for 1850-2100.

D. Validation and Model Improvements
A number of missing observational datasets can be readily identified that would speed-up and augment the carbon cycle model development. These include satellite measurements of column integrated CO₂, soil moisture, and vegetation structure as well as a general increase in the southern hemisphere data (e.g. carbon stocks, land use/management, surface ocean-atmosphere CO₂ fluxes).

The representation of agriculture (crop types, crop phenology, management including irrigation and tiling) and fire can clearly be identified as a weak point of many current models and requires further development.

Historical reconstructions of globally gridded land-use change including crop, pasture, shifting cultivation, and wood harvest have recently been completed for use in this class of models. A major need is the development of future global gridded-land use change products that are consistent with both the gridded historical reconstructions, and the future scenarios developed by scenario teams.

More constraints on the simulated carbon cycle are required to validate the models. These constraints could include observations or other methods (e.g. the Tracer Transport Model (TransCom) and Ocean Carbon Model Intercomprison Project (OCMIP) modeling strategies).

Ocean flux of CO₂ at the air-sea interface is likely to improve as eddies are resolved or as eddy mixing parameterizations are improved (e.g., through the use of ARGO float density, salinity and temperature information to validate models). In general, and as noted above, it is critical that the carbon cycle modelers identify critical aspects of the physical models that require further attention before realistic carbon cycle simulation can be achieved.
3. Proposed Experimental Design

The pathways of model development over the next ten years will not be parallel across groups. There are specific questions that will require high-resolution (in space, time, complexity) model runs, and those that will need to address longer-term questions with regard to impacts and mitigation. Therefore, we propose an experimental design that leverages near-term and longer-term model runs with appropriate classes of model complexity to address specific science questions.

I. Near-Term Experimental Design – Climate Change to 2030

A. Scientific Questions and Relevant Models

It is anticipated that model capability is now sufficient to provide some regional guidance as to the effects of climate change out to 2030. Of particular interest are regional changes in water availability (soil moisture), affected by changes in precipitation, evaporation and melting of the snow pack. Also of interest are local daily and seasonal temperature changes. With regard to societal impacts, it is the changes in extremes in both of these categories - floods, droughts, extended heat waves, hurricane frequency and intensity are primary concerns. Effects of climate change on human health, through alterations in air pollution (aerosols, ozone) or the migration and adaptation of disease vectors (e.g., carried by insects) could have significant societal impact. Many of these changes have ramifications for agriculture; in addition, climate change will also impact fishery industries. Conversely, the (unintended) consequences of large-scale conversion of forested and pastures to biofuels production on the coupled climate system are largely unkown. Stratospheric ozone recovery from chlorine loading will also impact the climate system during this time frame. In addition, an assessment of historical and near-term aerosol forcing, compared with on-going aerosol and temperature observations, may allow us to better understand aerosol climate forcing, and hence climate sensitivity.

Both AOGCM and ESM models will be useful for near-term simulations, although development of each requires significant computational and manpower resources. How to divide those resources remains an issue.

At one extreme, AOGCMs run at relatively high resolution (on the order of 0.5° for latitude and longitude) would allow for a better regional assessment of climate change and is necessary to simulate the statistics of observed storm systems that affect regional processes (Jung et al., 2006) as well as improved simulation of precipitation extremes (M. Wehner, personal communication), although additional downscaling to even finer resolution might be required for some climate change impact studies. Most AOGCMs currently have about 2° resolution. An increase of spatial resolution by a factor of 4 would increase computational time by close to a factor of 60. Additional increases in the vertical resolution, to optimize the dynamical advantages of the finer horizontal resolution, would bring the computational burden to greater than 100 times (i.e., two orders of magnitude). Such an approach would strongly inhibit the inclusion of additional physics to explore alternate aspects of the Earth system, some of which (aerosols, ozone, vegetation health) would be having direct effects on regional climate that would be omitted.

At the other extreme, ESMs could be run at close to the current resolution but with expanded physics packages for aerosol, atmospheric chemistry and dynamic vegetation. These additions likewise require significant computing time. Aerosol and atmospheric chemistry calculations can each double the computational time or add even more, depending on the sophistication of the routine. Simulations of stratospheric ozone chemistry could require greater resolution in the stratosphere and a higher top of the model. Their inclusion would allow for a more complete assessment of the physics of climate change, but would not provide more regional discrimination.

As a compromise approach, it is suggested that models for this time period utilize a somewhat finer horizontal resolution (on the order of 0.5º to 1º latitude/longitude) along with simplified aerosol and chemistry packages. Dynamic vegetation would be included to assess the health of the vegetation and possible in-place succession. Other longer-time scale processes, such as ocean biogeochemistry, land ice and ecosystem migration would be omitted or performed off-line since their feedbacks related to climate change operate on a longer timescale. A crude estimate is that for the various simulations suggested, even this model version would require some 4 dedicated computer-years using current computer capabilities, and developing finer resolution models is itself a non-trivial task. While the Japanese experience has been that their model parameterizations did not have to be changed (just tuned), and climate sensitivity was relatively invariant when going to significantly finer horizontal resolution, this has not been the
experience of, say, GFDL, and may not be true with much finer vertical resolution. Developing this new model may require significant time and resources prior to its use in these proposed experiments.

B. Relevant Emission Scenarios

Given that the different scenarios for well-mixed gases do not vary greatly prior to 2030, it is suggested that only one such scenario be employed. For aerosols and short-lived gases, several emission scenarios (including a low and a high estimate) should be provided. For example, consistent global, gridded data for reactive gases (CH₄, NOₓ, major classes of NMVOCs, CO, NH₃), aerosol precursors (SO₂), and aerosols (BC, OC) are needed. The ideal emissions input data set would:

1. Extend continuously from historical to future projection years
2. Be gridded at the finest resolution being considered (e.g. 0.5 degrees)
3. Exhibit appropriate spatial changes over time
4. Resolve appropriate injection heights (ground, 100m, aircraft)
5. Resolve large seasonal effects (biomass burning in particular)

Decisions on exactly what emissions are required will need to be made by the Earth system modelers, and providing these emissions will be the responsibility of Integrated Assessment modelers.

Some shorter-term projections (e.g. GAINS, RAINS, Streets et al.) produce emissions at a temporal and spatial scale that may be consistent with most of the ideal requirements listed. The integrated assessment models (IAMs) used to produce long-term emissions scenarios (up to 2100) generally produce emissions at a large spatial scale. The SRES exercise produced long-term emissions that were gridded at a level of four meta-regions, with a fixed pattern within each meta-region.

However, in general, producing consistent and globally gridded historical, near-term, and long-term input data sets is not a capability that exists at present. A first step toward this capability would be to conduct a census of available inventories and projections, their characteristics, and level of detailed data availability. Using this information, the actions and capabilities that would be needed to produce the necessary emissions data sets could be detailed.

The next generation of ESMs will also require scenarios of anthropogenic land use changes as input data. Gridded input data sets of land-use conversions (changes from one category to another) and management (agriculture, perhaps specific crops or classes of crops, forestry, pasture, etc.) will be needed. Methodologies to convert the output of IAMs to land-use change data sets that are consistent with the historical land-use change data sets used in the ESMs can carbon cycle models will also need to be developed. Ideally, biogenic emissions of VOCs would be produced by the ecosystem component of the ESM. In this manner, the effect of anthropogenic land-use and vegetation changes would be reflected in biogenic emissions. The same is true for methane, although this will likely remain in the research domain for the near future.

Additional experiments could be done to investigate suggested geoengineering attempts at mitigating climate warming. For this time frame, one option being discussed is that of injecting sulfur into the atmosphere, either into the stratosphere or troposphere, to help cool the climate. The climate consequences of such injections could be explored in ESMs; unintended consequences might be harder to ascertain.

C. Experimental Design and Ensembling/Scenario Simulations

Assuming the 'compromise' modeling approach is adopted, the attempt would be to provide the most realistic predictions possible for the regional scale. While the predictions would extend from the present to 2030, climate change over this time period is affected by what has happened in the past due to the committed warming in the system. The past decades will also provide the possibility of hind-casting, or evaluating the model for historic to current regional scale projections. These simulations will be affected by the initial conditions at the start of the experiment, particularly in the ocean (temperature, salinity) but also on land (soil moisture, ground temperature). Ocean initial conditions could conceivably be provided by ocean data assimilation exercises currently underway, and ideally using coupled initialization, but lack of observed salinity data sufficient for such a data assimilation exercise remain a significant problem. Additionally, there is no direct way to provide soil moisture or ground conditions at this time. The potential errors induced by incorrect initial conditions should become less important in
later years but could still be evident through the course of these simulations. If model simulations are started prior to the availability of the ocean initial conditions, the model ocean would have to be 'nudged' toward the observed values; how strongly this should be done, and what it implies about energy conservation are research issues that will have to be explored. There is also the science question of whether or not starting the model with something close to the present observed initial state matters, both in terms of decadal predictability, regional signal to noise, and climate change commitment.

In addition, as noted above, gridded emission data for aerosols and short-lived gases would need to be provided on this same fine regional scale, for both the historical times of concern as well as future projections. The "natural forcings" would be handled conservatively. The total solar irradiance for this time period could either remain unchanged, or specify an average observed 11-year cycle. The mean value for volcanic aerosol loading over the past 25 years could be employed, or a stochastic occurrence of major volcanoes, based on the last 100 years of data might be added.

To determine the significance of regional changes, especially those of extremes, will require numerous simulations in an ensemble approach. For this time frame the relatively small magnitude of climate change will make signal to noise discrimination even more difficult. We therefore propose that there could be one base-case scenario for the well-mixed gases along with low, medium, and high air pollution estimates (i.e., aerosol and short-lived gas emissions). The number of simulations to be performed is somewhat uncertain, but it should be at least 10-15 for the base case in order to discriminate changes in hydrologic extremes and to assess regional signal to noise for climate changes.

D. Initialization and Model Spinup Considerations

While historical simulations for spin-up and model evaluation are necessary, there are various factors to consider regarding the starting date for these runs. The atmosphere is in better radiative balance starting in 1950 than at later times, so starting the coupled initialization then should provide a better cumulative state of climate change commitment in the system. Ocean data initialization is currently being done from 1970 onward, although it is better in more recent years due to a larger number of observations; and emissions data improves greatly after 1980. The addition of the ARGO float data provide a better three-dimensional structure for ocean salinity after about 2004. However, the earlier the start time, the greater the computational burden being assumed. This may already be a problem (even without considering the longer-term simulations anticipated), and so the starting time may have to be 1980 for practical computing considerations.

II. Longer-Term Experimental Design – 2100 and Beyond

Longer-term runs provide an opportunity to contribute a policy perspective on avoiding the consequences of climate change in terms of stabilization strategies. In addition, experiments would provide a basis for evaluating the feedbacks and contributions of the carbon cycle to the climate system. The recommended experimental design indicates that WG1 and WG3 be staggered in time. The long-term simulations would be with lower resolution AOGCM and ESM’s (roughly 2°) with a pre-industrial spinup including a 20th century forced experiment that consists of natural and anthropogenic forcings. Two, possibly three greenhouse gas (GHG) and aerosol concentration scenarios would be supplied by WG3: (1) a high radiative forcing stabilization (e.g., A2-type), (2) a low radiative forcing stabilization (e.g., B1-type); and possibly (3) mid-range scenario (A1B-type) to provide a swath of possible outcomes. At least one ensemble member for each scenario would be considered, and the models would include as core, the terrestrial and ocean carbon cycle, biogeography and successional processes as implemented. Chemistry and aerosols would be prescribed to 2100 and stabilized after 2100 until 2300, although a few models may run interactive aerosols and chemistry as well. The first two experiments are considered 'core' for all groups to participate in, with a third, optional carbon cycle feedback calibration experiment. WG3 would provide time series of concentrations of GHGs for these experiments.
Figure 2: Schematic of traditional forward approach starting with socio-economic variables to derive emissions, concentrations and then temperature and other climate changes from climate models (top), and new proposed methodology where the starting point is concentrations run in climate models, that are used to derive emissions and then socio-economic factors to achieve those emissions. Traditionally, the forward approach is characterized by uncertainty (indicated by the wedge-shaped ranges for future climate) growing in the direction of the response of the climate system (i.e. left to right). The reverse approach, where anthropogenic emissions are equal to the difference between prescribed concentrations and simulated Earth system CO₂ fluxes shows uncertainty growing in the direction of the socio-economic factors required to achieve the concentration targets (i.e. right to left).

As noted in Fig. 2, using benchmark concentration scenarios as the starting point is different from the more traditional starting point of socio-economic variables used to derive emissions, and then concentrations that are run in the models (left to right in the top part of Fig. 2). However, by using benchmark concentration scenarios that are then applied to derive emissions and then socio-economic factors to achieve them (right to left in lower part of Fig. 2), WG1 does not have to evaluate socio-economics before running scenarios in climate models, and WG3, who have expertise in socio-economics, can determine the factors that would produce the emissions from the concentrations that have an associated climate change outcome. There will be multiple socio-economic pathways leading to the concentrations resulting in a rich ensemble of WG3 scenarios.

It is important that any proposed set of integrations be easily integrated by non-ESM (AOGCM) models. This will allow groups who do not have an ESM to participate in these experiments. The number of proposed integrations is also important. Due to the large amount of computer resources required to time integrate ESMs, it is important to prescribe only a few required integrations. Groups are always free to integrate other scenarios and other models (e.g. including ice sheet models), but these would be for research and not part of the common set.

A second type of constraint involves the scenarios used to drive the ESMs. Policymakers are increasingly focused on stabilization scenarios and the ways to achieve climate stabilization. All proposed scenarios assume stabilization after 2100. To implement this strategy, experiments are proposed which use given benchmark concentration scenarios that represent a high and a low radiative forcing.

**Control Simulation (required):** This is a long-term control run for diagnosing model drift in terms of climate and carbon fluxes.
**Experiment 1: Long-term benchmark stabilization:** An AOGCM or ESM is run with time series of specified benchmark concentrations provided by WG3. The idea is to use prescribed concentrations of the GHGs and aerosols (Note: Aerosol concentrations will depend on spatial emissions patterns, these will have to be specified for the scenarios, as was the case in SRES. How these are developed and by whom needs to be determined; In the case of SRES this was a joint WG1 and WG3 effort). Each scenario would also include the prescribed changes in the future land use in accordance with the scenario characteristics. The ESMs would be initialized in a manner similar to what was used in AR4. After the model is developed, the radiative forcing constituents are set to “pre-industrial” (usually mid-1800s) conditions. The model is allowed to come into a quasi-equilibrium state with those radiative conditions (usually after several centuries of integration). At some point in this integration, the start of the pre-industrial control is declared (i.e. year 1 of the pre-industrial control). One evaluation criterion to be used for the fidelity of the carbon components will be the rate of drift of the carbon system in this control (e.g. some modelling groups try to achieve long-term mean land-atmosphere and ocean-atmosphere fluxes of CO₂ within 0.2 GtC/yr of zero net flux). However, the 10% level of the current sink is not totally relevant here. The main point is that the long term mean of the sum of land and ocean fluxes should be close to zero (0.1 to 0.2 GtC/yr). The sum is what really matters for 2 reasons: a) in the ‘real world’, there is a net CO₂ flux from the land to the ocean through rivers, this means that the net atmosphere-land flux is a sink and the net atmosphere-ocean flux is a source, but the sum of the two is zero; b) emissions will be function of the sum of the ocean and land fluxes, and any long term imbalance in the land-ocean flux will translate to a non-zero emission. As in the AR4 exercise, it would be good to have a long control run from the ESMs in order to estimate the carbon drift, and remove it from the inferred emissions for a given scenario if necessary.

At various points in the pre-industrial control, historical integrations of 20th century climate can be started to generate an ensemble. This ensemble is useful for detection/attribution studies and other comparisons to the observed climate changes. The inputs needed for this type of integration are the time series of anthropogenic (GHG, ozone, and aerosol concentrations and land use changes) and natural (solar and volcano) forcings. This is similar to what was done for the coordinated integrations assessed by the IPCC AR4.

The future projections start from the end of the historical integrations. The concentrations of GHGs (including CO₂) and aerosols and the future land use changes are prescribed according to the input scenario (see below for details). The prescribed atmospheric CO₂ concentrations are used in the radiation calculation and to compute the carbon fluxes from the land and ocean. This prescription allows non-ESM models to be forced in a manner similar to the ESMs and allows for easier intercomparison of the physical climate response among all the models in the common set.

The ESMs that include an interactive carbon cycle will calculate land and ocean CO₂ fluxes which are the response to the prescribed CO₂ concentration scenario and the climate change as a result of those changing concentrations. These CO₂ fluxes do not enter the atmosphere, so the atmospheric temperature responds only to the prescribed concentrations. The CO₂ fluxes are saved and, in combination with the prescribed CO₂ concentrations, are used to calculate the “permissible CO₂ emissions” time series using an approach already adopted applied to some first generation coupled climate-carbon cycle models (Jones et al., 2006):

\[ E(t) = \frac{dCO_2}{dt} + F_{A,O} + F_{A,L} \]

where \( E(t) \) is the time series of anthropogenic emissions calculated from the prescribed rate of carbon dioxide concentration increase \( \frac{dCO_2}{dt} \), and the modelled atmosphere-land and atmosphere-ocean fluxes of CO₂ are \( F_{A,O} \) and \( F_{A,L} \) respectively. This applies to models not computing land use change fluxes, so, e.g. carbon fluxes from deforestation would be lumped in with those from fossil fuel burning. Other models could estimate carbon fluxes from imposed land use changes as part of the last term on the right, and the residual would be only from fossil fuel. The profile of permissible emissions diagnosed from each ESM can be used by IPCC WG3 to determine the policy measures consistent with the prescribed concentration scenario and the particular model projection. In some cases the permissible emissions may not be feasible, or could be inconsistent with the assumptions implicit in the concentration scenario (e.g. by assuming land-use changes that are inconsistent with the implied net CO₂ emissions). Here a WGIII-WGI-WGIII iteration could be desirable to derive achievable stabilization scenarios. Related guidance on the realism or otherwise of stabilization scenarios will be very useful information for policymakers.
That is, the rate of change of CO₂ concentration (which is prescribed) is \( \frac{dC}{dt} = F_{\text{emissions}} - F_{\text{o-a}} - F_{\text{l-a}} \), or, the change in CO₂ with time = emissions minus CO₂ fluxes from the ocean-atmosphere and land-atmosphere. The WG3 scenarios group would also provide prescribed concentrations for other gases as well as aerosols that would be used by the models.

The stabilization concentration scenario produces climate change with either an AOGCM or an ESM, whereas diagnoses for the carbon cycle and compatible emissions are performed by either an ESM or offline carbon cycle model.
Figure 3. Schematic of Experiment #1. The carbon cycle sees increasing CO2 concentrations and resulting changes in temperature. The land and ocean CO2 fluxes are saved to derive emissions for WG3 scientists. The land and ocean CO2 fluxes are saved for that purpose and do not enter the atmosphere to influence the atmospheric concentrations. Computed compatible anthropogenic emissions are equal to the prescribed atmospheric CO2 concentration changes plus Earth system (land + ocean) CO2 fluxes. Since the concentration changes are prescribed and the fluxes are computed in the model, the experiment allows the calculation of the model-dependant compatible anthropogenic emissions.

Experiment #2: Carbon cycle response to increasing concentrations: A second integration is designed to evaluate the impact of the changes in prescribed atmospheric CO2 on the carbon cycle response. For this experiment, atmospheric CO2 is fixed for the radiation code in the atmospheric model only. That is, the atmosphere sees a constant CO2 concentration throughout the experiment. Therefore, no forced climate change occurs, and the temperature response to that constant CO2 will remain about the same throughout (except for internal climate variability and climate change commitment). However, the CO2 concentrations from Experiment 1 are seen by the carbon cycle component, and the resulting CO2 fluxes are saved as they were in Experiment 1, but the carbon cycle only responds to the increasing CO2 since the temperature remains about the same. Consequently, the CO2 fluxes from the carbon cycle (along with the specified concentrations) can be used to derive emissions, and the difference between the two derived time series of emissions in experiments 1 and 2 is a measure of the carbon cycle feedback in terms of emissions (emissions consistent with a given concentrations scenario). The CO2 concentrations from Experiment 1 are very important, since the impact of emissions on stabilization at a given level for a given benchmark scenario provides WG3 with information regarding which socio-economic options would be required to reach that level of stabilization. The derived emissions likely will be noisy, and WG3 will have to fit, or smooth the time series of emission pathways.
Figure 4. Schematic of Experiment #2. The carbon cycle (land and ocean) sees CO2 concentrations from Experiment #1 (top left). Atmospheric CO2 is held constant for the radiation calculation so there is little temperature change (top right). Earth system (land and ocean) CO2 fluxes are saved to derive emissions (lower) for the integrated assessment modeling groups. The land and ocean CO2 fluxes are NOT radiatively interactive with the atmosphere. Anthropogenic emissions from experiment 2 (blue line in lower panel) are calculated as in experiment 1 (red line in lower panel) where the change in anthropogenic emissions is equal to the prescribed atmospheric CO2 changes plus Earth system (land + ocean) CO2 fluxes. Calculation of carbon cycle fluxes and compatible emissions are simulated by ESMs or offline carbon cycle models. The difference in emissions between experiment 2 and experiment 1 represents the effect of carbon cycle feedbacks on compatible emissions for a given stabilization concentration scenario.

A minimum of two stabilization concentration scenarios are required to be integrated by the models: a high and a low case, with the possibility of a medium range case. As noted above, these are all GHG stabilization scenarios. The high case could stabilize near 700 ppm CO2 (or about 950 ppm in terms of equivalent CO2) concentration in the atmosphere corresponding to about 6.5 W/m2 radiative forcing relative to present day. The low case could stabilize near 400 ppm CO2 (or about 500 ppm equivalent CO2) concentration corresponding to about 3 W/m2. Each scenario would take into account land use changes changes (and other driving forces) consistent with the GHG emission profiles.

**Experiment 3: Emissions-Driven Carbon Cycle/Climate:** Though still under discussion, this simulation is designed to evaluate ESM response to climate change that is driven by emissions rather than concentrations. One option for this experiment would be to prescribe a standard emissions time series (comparable to the idealized 1% per year CO2 increase experiments run with AOGCMs) with a fully interactive carbon cycle. Each model will produce a slightly different concentration trajectory and result in different climate changes that represent the carbon cycle feedback compared to the standard 1% per year CO2 increase experiment in terms of quantities like temperature. This would provide a direct connection to simulations from the C4MIP experiments as well as to the standard idealized 1% per year CO2 increase experiments run with AOGCMs. Another possibility being discussed for this experiment would be to take the emissions used to derive the benchmark concentration scenarios in experiment 1, run the fully coupled ESMs with those emissions, and compare the climate response to experiment 1 to assess the magnitude and nature of the climate feedbacks involved with the carbon cycle.
If a modeling group has only an AOGCM (i.e. no carbon cycle), the near-term and/or the long term Experiment 1 could still be run to obtain climate change outcomes, thus widening the participation. This experimental design also provides consistent analyses across models such that caveats of model-specific inputs will not have to be documented later. Results from AOGCMs can be directly compared with the ESMs for the physical climate system response. WG3 scientists would supply the benchmark concentration scenarios to the modeling groups. In turn, WGI modeling groups would supply emission time series back to WG3 to derive socio-economic considerations to achieve those emissions stabilization pathways.

These experiments are designed to be community-coordinated, and do not rule out different experiments with different scenarios and different model formulations that could be run by individual modeling groups. This experimental design allows an ESM to diagnose the feedback of the carbon cycle in terms of emissions from Experiments 1 and 2, and Experiment 3 explores the quantification of the carbon cycle feedback in terms of climate change. This experimental design also provides consistent analyses across models such that caveats of model-specific inputs will not have to be documented later.

Advantages of a three-phase long-term stabilization approach include:

1. Relatively few future climate projections required of the ESMs. In AR4, three future integrations were integrated by most groups. The two required benchmark integrations per scenario with two required scenarios yield four future integrations (with the optional fully coupled carbon cycle feedback experiment 3, and a possible mid-range scenario experiment). Modeling groups that have only an AOGCM would have only two required future integrations.
2. AOGCM results can be directly compared with ESM results for the physical climate system as in AR4.
3. Using benchmark scenarios allows the WGIII community to supply new scenarios to the WGI community in a timely manner. The development of a complete new set of scenarios would take place in parallel to the climate modeling groups running the benchmark concentration scenario experiments. At the same time, WGI and III can use the climate outcomes of benchmark scenarios to better assess the resulting impacts and possible mitigation and adaptation measures and policies. All of this together can help improve the integrated assessment models.
4. The process involved with this experimental design establishes pathways for the necessary interactions between the WGI, WGII and WGIII communities and shortens the time frame required for developing new scenarios and climate projections.

5. **Overall Recommendations**

- The development of Earth System Models (ESMs) prompts addressing a new set of scientific questions with a coordinated set of experiments that could also be assessed as part of a possible Fifth IPCC Assessment (AR5). Here we view this generation of ESMs to include components of the terrestrial and ocean biology to close the carbon cycle. The ESM may include other components such as atmospheric chemistry, prognostic aerosol components or dynamic vegetation. The input scenarios should supply information (emissions or concentrations) so that models of varying sophistication can be integrated. Gridded land use changes must also be incorporated. Ice sheet components will likely be included in experimental versions of the models but are not included in the coordinated experiments.
- An integrated effort is needed to produce past/current/future emissions of aerosols and ozone precursors to ensure the use of consistent and documented data relevant to climate/carbon cycle/aerosol/chemistry communities.
- To assess regional effects in short-term predictions will also require gridded emission data for aerosols and short-lived trace gasses as well as land use. A concerted effort will be necessary to produce these datasets.
- For longer-term runs, ideally the WG2 and WG3 IPCC reports need to be lagged about 2 years behind a WG1 report. At present, the WG2 and WG3 reports use relatively outdated (up to six years) model simulations from the previous assessment while WG1 uses relatively outdated emissions scenarios. It
would be more desirable if all three working groups are using as close to current generation model projections as possible. An alternative would be for the modeling groups to make new climate change projections with benchmark concentration scenarios as soon as possible (about the 2009-2010 timeframe), and delay the next full assessment by about 2 years (to 2015).

- There is a need for a PCMDI equivalent for WG2 and WG3 communities, or an expanded role for the IPCC DDC, and a WGCM-type community organizing mechanism for WG2 and WG3.

- WG2 and WG3 need to have input to selection of fields to be archived for analysis in the new integrations, in particular a list of fields related to the carbon cycle.

- Earth System Models of Intermediate Complexity (EMICs) could be used to interpolate between the benchmark scenarios, or to run many more stabilization scenarios that will be generated by the IA modeling groups.

6. Emerging Issues

After the joint WGCM/AIMES meeting in Victoria, B.C., Canada, in September, 2006, a number of issues were raised, first where there was agreement with the strategy posed so far, and where there were science questions related mainly to the short-term experiment:

Agreement so far for long term experiments:

- A “reverse approach” for scenarios with WG3 supplying a few benchmark concentration scenarios, and WG1 supplying emissions back to WG3 to derive socio-economics.
- Experiments 1 and 2 for long term climate to get carbon cycle feedback in terms of emissions, and carbon cycle calibration experiment
- Option for AOGCMs and ESMs to participate

Science Questions for short term experiments:

- Does a coupled initialized observed state matter? (i.e. Is there decadal predictability from an observed initial state that would improve projections for the 25 year time frame?)
- What is signal to noise for climate changes on the regional space scale for the 25 year time scale? Would such changes be detectible?
- Is time-evolving chemistry necessary or time slice, and/or how important is time-evolving chemistry/aerosols for regional climate change?
- Is it better for more ensemble members and lower resolution, or fewer ensemble members and higher resolution?
- What about details of land use change (e.g. need to coordinate land use changes in IA models, carbon cycle models, and ESMs)?
- In lieu of chemistry, specified stratospheric ozone?

Current status:

- An abbreviated summary version of this white paper has been published in EOS (Hibbard et al., 2007), and this white paper includes more detailed descriptions and discussions. The EOS article and this white paper are to receive wide distribution throughout the WCRP and IGBP communities, and comments are being solicited from the modeling community regarding the proposed experimental design.
- The proposed strategy will be considered over by the relevant communities, and research will occur to address issues raised by the science questions involved with the strategy.
- The approaches and issues involved with ESMs are new to the WCRP community and need time to consider; therefore revisit this plan and revise/alter as needed at the next WGCM meeting (September, 2007, Hamburg).
d. Research activities: short term regional signal/noise quantification; coupled initialization and decadal predictability; EMICs used to test feasibility of experimental design, with possible low resolution ESM experiments to follow.

e. Currently, there are several venues where this strategy will be further discussed and developed:
   i. An Integrated Assessment Model Scenarios meeting early August, 2007 to coordinate land-use datasets with WG1,
   ii. An IPCC Expert Scenarios Meeting: ‘Towards New Scenarios for Analysis of Emissions, Climate Change and Response Strategies’. The meeting will be held in Noordwijkerhout, The Netherlands, 19-21 September 2007, and will be hosted by the Dutch Government. The objective of this meeting is to identify requirements and plans for the development of new scenarios of emissions, climate change, and adaptation and mitigation (including underlying socio-economic conditions that shape emissions and vulnerability), and to recommend the benchmark concentration scenarios for use in the experimental design described in this report. The scenarios will be of interest to the research and user communities, and will assist in the coordination of research assessed in a possible IPCC Fifth Assessment Report (AR5). The meeting will provide a unique forum for various groups and scientific communities to meet and discuss plans and coordination requirements for new scenario development.

f. There is probably a need for a similar activity to engage WG1 and WG2 scientists as well as the observing network communities that addresses lessons learned from the AR4 towards reducing uncertainties in the climate system observations and projections. A joint WCRP/GCOS and IGBP workshop will be held in Sydney, early October to establish future observing system and climate change research requirements based on gaps and uncertainties identified from the IPCC Fourth Assessment Report’s (AR4); to determine observation and research requirements that lead to better climate change risk analyses and adaptation measures; and result in lower vulnerability and impacts to a changing climate; and to outline observation and research priorities for possible input into future IPCC assessments with regard to risk management/vulnerability issues.
